Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICIAN," OCTOBER 26, 1900.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XLV.

(Second Series.)

FROM APRIL 27, 1900, TO OCTOBER 19, 1900.

ALL RIGHTS RESERVED.

LONDON:

Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1900.

Paris Exhibition—*Continued.*
Breakdowns, 77, 355
British Engines and Dynamos, 550
Chambers of Commerce Congress, 791
Commercial Information Office, 647
Congress of Electricity, International, 213, 820, 842, 877, 889. (*Erratum*) 840 (*see also* Index of Papers read before Societies)
Fire, 121
French Alternating Current Sets, 844, 886
French Continuous Current Sets, 663
General Electrical Features, 470
German Dynamos and Engines, 694, 768
Institution Visit, 162, 204, 544
Iron and Steel Institute, 624
Light and Power Supply, 507
Literature, 205, 727, 752, 878
Notes by our Correspondent, 108, 151
Patents, 50
Physics Congress, 206, 544
Psychology Congress, 656
Reno Inclined Elevator, 592
Students, Grants to, 469
Swiss Generating Sets, 917
Tramways Congress, International, 3

PARLIAMENTARY INTELLIGENCE—
Acts of Parliament, List of New, 81, 230, 623, 647
Afghanistan, Telegraphs in, 233
Baker Street and Waterloo Railway Bill, *37*, 61, 452
Batley Corporation Tramways Bill, 570
Blackpool, St. Anne's and Lytham Tramways Bill, 191
Bournemouth Corporation Tramways Bill, 340
Bray and Enniskerry Railway Bill, 377
British Colonies, Cable Communication Between, 491
Brompton and Piccadilly Circus Railway Bill, 529
Cable to Wei-Hai-Wei, Proposed, 491
Camborne and Redruth Tramways Bill, 376
Charing Cross and Strand Electricity Supply Bill, 62, 106, 449
Christchurch, Bournemouth and Winton Tramways Bill, 219
City of London Electric Lighting Co.'s Bill, 149, 379, 454
County of Durham Electric Power Bill, 58, 61, 104, *119*, 150, 186, 491, 529
Croydon Tramways and Improvement Bill, 339
Dublin Electric Lighting Bill, 188, 378, 412
East Ham Tramways Bill, 413
East London Electric Lighting (Limehouse, Mile End and St. George's-in-the-East) Orders, 413, 488, 517
Edinburgh Corporation Bill, 523
Electricity and Potato Culture, 415
Factory and Workshops Bill, 66
Ilfracombe and Totland Bay Electric Lighting Order, 378
Jarston Tramways Bill, 415, 572
Glasgow District Tramways Bill, 225, 491, 517
Gosforth Electric Lighting Order, 378
Government Telegraph Messages, 149
Great Grimsby Street Tramways Bill, 63
Halifax Corporation Bill, 191
Hamilton, Motherwell and Wishaw Tramways Bill, 414
Hastings Tramways Bill, 454
Huddersfield Corporation Tramways Bill, 106, 191
Imperial Telegraphs, 550
Lancashire Electric Power Co.'s Bill, 81, 188, 219, 336, 570
Lincoln Corporation Tramways Bill, 414
Liverpool Overhead Railway Bill, 191, 491
London County Council Tramways Bills, 339, 374, 528, 569
London, Walthamstow and Epping Forest Railway, 343
London United Tramways Bill, 106, 452, 491
Manchester Corporation Tramways Bill, 190, 529
Manchester and Liverpool Express Railway Bill, 75, 107, *119*, 146, 189
Marylebone (London) Provisional Electric Lighting Order, 412
Mersey and Wirral Railway Bills, 191, 453
Metropolitan District Railway Co.'s Bill, 149, 490
Municipal Trading, 61, 151, 191, 227, 335, 373, 451, 516, 563, 613, 831
Musselburgh Electric Tramways Bill, 377
National Physical Laboratory, *76*
National Telephone Company and Glasgow Corporation, 612
Naval Boiler Committee, 588
North Metropolitan Electric Power Supply Bill, *75*, *207*, 217, 338, 412, 450, 572
Pacific Cable, The, 454
Post Office and the Telephone, *37*, 59
Preston Corporation Tramways Bill, 454
Private Bill Legislation, 27, 67, 110, 647
Provisional Order Transfers, 454
Plymouth, Stonehouse and Devonport Tramways Bill, 376
Railway Companies and Electric Tramways, 530
Reading Corporation Tramways Bill, 375
Rochdale Corporation Tramways Bill, 296, 528
Sandgate and Hythe Tramroad Bill, 226
Shannon Water and Electric Power Bill, 411, 529, 570
Sheffield Tramways Bill, 454

Parliamentary Intelligence—*Continued*
Southampton Tramways Bill, 415, 572
South Eastern and Chatham Railway Co.'s Bill, 226
South Eastern Metropolitan Tramways Bill, 107, 415, 454
South Lancashire Electrical Tramways Bill, 62, 376, 415, 453
South Staffordshire Tramways Bill, 415
Southport and Lytham Tramroad Bill, 190
South Wales Electrical Power Distribution Bill, 57, 338, 377, 411, 569
Telegraphic Communication, Imperial, *159*, 184
Telephone Wayleaves in London, *37*, 59
Telephonic Competition, 491
Telephoning Telegraphic Messages, 355, 379
Tottenham District Council Bill, 340
Tramways Construction, Local Authorities and, 613
Twickenham Provisional Electric Lighting, Order Bill, 340
Tyneside Electric Power Bill, 80, 105, *119*, 150, 186
Underground Telegraph Cables and Wires, 61, 151, 340
Vale of Rheidol Light Railway Bill, 415
Walsall Corporation, 490
Warrington Corporation Tramways Bill, 414, 571
War Office Contracts, 338
Weston-super-Mare Tramways Bill, 376, 414, 529
Wellingborough and District Tramroads Bill, 374
West Ham Corporation Bill, 378
West Bromwich Corporation Bill, 227, 451
Wireless Telegraphy, 233, 451, 491

PARRY, E.: Fall of Potential Along Tramway Rails, 595
Parsons' Steam Turbine Abroad, 39
Parsons' Turbo-Alternators, 494
Partick, 153
Patent Amendments, 347, 496, 650, 975
Patent Office, Annual Report of, *160*
Patent Office Library, 545
Patent Record, 30, 113, 348, 387, 421, 461, 496, 532, 579, 617, (51, 685, 721, 757, 797, 835, 873, 944, 979

Letters to the Editor.

Absorption of Electric Waves	FLEMING, J. A., 222
Adjustable High Resistances	DAVIDSON, A., 372
Artificial Production of Diamonds	"W. G. C.," 296
B.E.T. Superannuation Fund Association	GARCKE, E., 378
Carbon Filaments and Lightning Flashes	LANGDON, W., 828 BLACKMORE, S. P., 828 ANDREWS, W. S., 868 TAYLOR, F. ALEX., 904
Coherers	LODGE, OLIVER J., 933 BOSE, J. C., 972
Current Rushes into Transformers	HAY, ALFRED, 333
Damage to Cables by Storms	C. AND A. MUSKER, 644
Efficiency of the Continuous Current Arc	AYRTON, W. E., 972
Electrical Conductors and Dirt	SWINTON, A. A. C., 679
Electric Boats for the Thames	ECK, JUSTUS, 263
Electric Traction Currents and Submarine Cable Working	HAY, ALFRED, 224 SCHAEFER, C. W., 372
Electric Traction under British Conditions	SAYERS, HENRY M., 296
Electrolysis by Traction Currents	CARDEW, P., 868
Enclosed Arc Lamp Patents	JANDUS ARC LAMP AND ELECTRIC CO., 612 DAVY, W. J., 644
Extended Pole Pieces	THOMSON, ELIHU, 137
Gas Engine Electric Supply Stations	CROSSLEY BROS., 525
Guarini's Wireless Telegraph Repeater	GÉRARD, E., 224
High Voltage Transmission	DOUGLAS, C. H., 137
Long Distance Transmission of Power	PERRY, JOHN, 223, 295 FORBES, GEORGE, 263, 332 SWINBURNE, JAMES, 294 CARUS-WILSON, C. A., 294 TAYLOR, A. M., 333 WOOD, REGINALD, 428
Matthiessen's Standard	EVERETT, J. D., 59 HOWARD, A. H., 59 CAMPBELL, ALBERT, 96
Motor-Testing Cradle	JERVIS-SMITH, F. J., 296
Single-Phase Alternating Current Motors	W. LANGDON-DAVIES, 525
Southport Tramways	MACARTNEY, MCELROY & CO., 612
Sparking Phenomenon	J. VON GEITLER, 525
Steljes' Typewriting Telegraph	SPAGNOLETTI, C.E., 410
Stimulating Demand for Electricity Supply	LYON, HENRY, 458
Tramways and Light Railways Exhibition	WITTING BROS., 410
Transparency of Liquids to Electric Waves	FLEMING, J. A., 487
Wireless Telegraphy	MARCHANT, E. W., 568

Digitized by Google

Scientific Societies—Papers, &c., read before.

American Institute of Electrical Engineers.

Wave Transmission over Non-uniform Cables and Long-Distance Air Lines, 598 (*see also pages 242* and *587*) ..... Pupin, Dr. M. I.

British Association.

A Combination Integrating Wattmeter and Maximum Demand Indicator, 862 ..... Barker, J. H.
An Experiment on Simultaneous Contrast, 804 ..... Burch, G. J.
An Improved Standard Resistance Coil, 772 ..... Whipple, R. S.
Electromotive Force of a Moving Charge, 763 ..... FitzGerald, Prof. G. F.
On the Apparent Emission of Cathode Rays from an Electrode of Zero Potential, 773 (*see also page* 782) ..... Phillips, C. E. S.
On the Phosphorescent Glow in Gases, 936 ..... Burke, J. B. B.
On the Similarity of Effect of Electrical Stimulus on Inorganic and Living Substances, 774, 861, 897 (*see also page 780*) ..... Bose, Prof. J. Chunder
On the Vector Potential of Electric Currents in a Field where Disturbances are Propagated with Finite Velocity, 867 .. Burbury, S. H.
Power Generation: Comparative Cost by the Steam Engine, Water Turbine and Gas Engine, 970 ..... Kershaw, J. B. C.
Presidential Address to Geographical Section, 787 (*see also page 768*) ..... Robertson, Sir G. S.
Presidential Address to Section A, 732, 784; (*Erratum*) 763.. Larmor, Dr. Joseph
Recent Tramway Construction with Special Preference to the Demerbe System, 924 ..... Dawson, William
The Design and Location of Electric Generating Stations, 864 Gibbings, A. H.
The Manchester-Liverpool Express Railway, 863 (*see also page* 782) ..... Preece, Sir W. H.
The Production of an Artificial Light of the same Character as Daylight, 777 ..... Dufton, A. and Gardner, W. M.
The Propagation of Electric Waves along Parallel Wires, 803.. Morton, W. B.
The Use of Multiple Space in Applied Mathematics, 864..... Carslaw, H. S.
Wireless Telephony, 773 (*see also pages 761* and 782) ..... Preece, Sir W. H.

Cambridge Philosophical Society.

The Genesis of the Ions in the Discharge of Electricity through Gases, 736 ..... Thomson, Prof. J. J.

Institution of Civil Engineers.

The Relations between Electricity and Engineering ("James Forrest" Lecture), 18 (*see also pages 2* and *16*) ..... Preece, Sir Wm. H.

Institution of Electrical Engineers.

A Frictionless Motor Meter, 283, 328, 438, 513; (*Discussion*) 562 Eversheds, S.
Alternating-Current Induction Motors, 642, 675, 708; (*Discussion*) 744.... Eborall, A. C.
On Distant Electric Power Transmission, 49, 85; (*Discussion*) 129; (*Correspondence*) 137, 223, 262, 294, 332 (*see also pages 37, 134, 273*) ..... Forbes, Prof. George.
The Calculation of Distributing Systems of Electric Traction under British Conditions, 179, 255; (*Discussion*) 259; (*Correspondence*) 295 (*see also page 254*) ..... Sayers, H. M.
The Electrical Equipment of Ships of War, 8, 45, 127, 177, 214; (*Discussion*) 216 ..... Grove, C. E.

Glasgow Section.

Some Considerations Concerning Electric Driving, 233; (*Discussion*) 291..... Mavor, H. A.

Newcastle-on-Tyne Section.

Presidential Address, 247 ..... Heaviside, A. W.

Institution of Mechanical Engineers.

Electric Road Locomotion, 361 ..... Hele-Shaw, Prof. H. S.

International Electricity Congress (Paris).

A Practical Telegraph Transmitter using the Sine Wave for Operating the Wheatstone Receiver, 744 (*see also pages 726* and 892) ..... Crehore, A. C. and Squier, G. O.
Electric Furnaces, 861 (*see also pages 839* and 889)..... Keller, M.
Fuel for Gas Motors, 934 ..... Witz, Prof. A.
On the Construction of Dynamo-Electric Machines, 930 (*see also page 913*) ..... Leblanc, Maurice.
Photometry, 858 (*see also page 856*) ..... Violle, J.
The Accurate Measurement of Alternating and Multiphase Currents, 901 (*see also page* 821) ..... Addenbrooke, G. L.
The Light Emitted by the Continuous Current Arc, 921, 966 (*see also pages* 843, *928*, *949* and 972) ..... Ayrton, Mrs.
The Use of Condensers, 935 ..... Boucherot, P.

Municipal Electrical Association.

Combined Management of Tramway and Lighting Departments, 521 ..... Quin, R. C.
Electricity Supply for Small Towns, 370; (*Discussion*) 448; (*Correspondence*) 525 (*see also pages* 325, *444*, *467*) ..... Brown, C. S. Vesey.
Impressions of American Tramway Practice, 711 (*see also page* 362) ..... Le Rossignol, A. E.
Means of Stimulating the Demand for an Electricity Supply, 330, 331; (*Discussion*) 363; (*Correspondence*) 458 (*see also page* 325) ..... Potter, Alderman. Bishop, H. Collings.
Notes on the Maintenance of Motors on Hire from an Electricity Works, 473 (*Discussion*) 481; (*Correspondence*) 525 Prusman, C. A. L.
On the Maintenance of Certain Portions of Distributing Systems at Earth Potential, 638; (*Discussion*) 640 (*see also pages* 362 and *634*) ..... Wordingham, C. H.
Power Supply by Single-Phase Motors, 408; (*Discussion*) 481; (*Correspondence*) 525 (*see also pages* 362 and 482) ..... Wilmshurst, T. P.
Presidential Address, 320 (*see also page 399*) ..... Mountain H. B.
The Distribution of Electricity, 698; (*Discussion*) 610 (*see also page 602*) ..... Wilkinson, G.
The Distribution of Electricity to Scattered Areas, 605; (*Discussion*) 610 (*see also page 602*) ..... Andrews, L.
The Lighting of Small Towns, 393; (*Discussion*) 448; (*Correspondence*) 525 (*see also pages* 325 and *444*) .. . . Harriss, G. M.
The Reduction of Light Load Losses in Alternating Supply Works, 559; (*Discussion*) 592 (*see also pages 558* and *602*) Boot, Horace.

Physical Society.

A Comparison of Impure Platinum Thermometers, 365 ..... Tory, H. M.
An Application of the Method of Strie to the Illumination of Objects under the Microscope, 292 ..... Wood, Prof.
A Short Account of the Physical Problems now being Investigated at the Solar Physics Observatory, and their Astronomical Application, 98 ..... Lockyer, Sir Norman.
Electromagnetic Experiment, 176 ..... Thompson, Prof. S. P.
Experiments Illustrating the Aberration called Coma, 291 .. Thompson, Prof. S. P.
Note on the Crystallisation Produced in Solid Metal by Pressure, 292 ..... Campbell, W.
Notes on Gas Thermometry, 365..... Chappuis, Dr. P.
Notes on the Measurement of some Standard Resistances, 291 Glazebrook, R. T.
On the Controversy concerning Volta's Contact Force (*Discussion*), 176 ..... Lodge, Prof. O. J.
On the Strength of Ductile Materials under Combined Stresses, 292 ..... Guest, J. J.
The Heat of Formation of Alloys, 176 ..... Tayler, J. B.
The Law of Cailletet and Mathias and the Critical Density, 365 Young, Prof. S.
The Magnetic Properties of Alloys of Iron and Aluminium (Part II.), 292..... Gladstone, Dr. J. H.
The Viscosities of Mixtures of Liquids and Solutions, 292 .... Lees, Dr. C. H.
The Want of Uniformity in the Action of Copper-Zinc Alloys on Nitric Acid, 176 ..... Gladstone, Dr. J. H.

Railway Signalling Club.

Failures of Automatic Block Signals Due to Lightning, 841 .. Miles, H. D.

Royal Institute of British Architects.

The Protection of Buildings from Lightning, 20. ....Hedges, Killingworth.

Royal Institution.

A Century of Chemistry at the Royal Institution, 56, 93, 135, 175 Dewar, Prof. J.
Nineteenth Century Clouds over the Dynamical Theory of Heat and Light, 56 ..... Kelvin, Lord.
The Structure of Metals, *161*..... Ewing, Prof. J. A.

Society of Arts.

Imperial Telegraphic Communication, 225 (*see also page 203*) Sassoon, Sir E. A.

Society of Dyers and Colourists.

Electrochemistry in a Dye and Print Works, 703 ..... Sunderland, A. E.

Society of Engineers.

Electric Traction, 275 .. .. Binyon, A. H.
The Economical Disposal of Town Refuse, 77..... Healy, Brierley.

Tramways and Light Railways Association.

Electric Tramway Power Station Design, 529 ..... Dawson, Philip.
Work of the Light Railway Commission, 430 ..... Scotter, R. H.
Profits on Tramway Undertakings, 657 ..... Gadsby, C. H.

NOTES.

THE ways of magistrates are often mysterious and their humour past comprehension. Mr. PLOWDEN, at the Marylebone Police Court, on Tuesday, raised an inexplicable laugh by the remark that "the electric light seemed to have flitted over the parish with the fitfulness and brilliancy of summer lightning: one never knew when it was coming." All because the Metropolitan Electric Supply Co. had not been able at all times to meet the enormous demand for current. He thought the company's explanations as to failure during the past year exculpated them from blame, but all the same he ordered the company to pay £1. 5s., and 10 guineas costs, on the original summonses to which they had pleaded guilty. Contrast this with the fate of the London Electric Supply Corporation at the Southwark Police Court on the same day. Mr. PAUL TAYLOR, without indulging in irrelevant jocularity, admitted the company's plea of *force majeure* and dismissed the summonses. At the Greenwich Police Court the same company advanced the same plea, but the magistrate reserved his decision until the 4th prox.

THE new Tramways and Light Railways Association, which enjoyed its inaugural dinner at the Hotel Cecil last Wednesday, should prove a valuable centre of tramway and kindred interests—and incidentally of electric traction—in this country. About two hundred members and guests assembled at the feast, which was under the presidency of Sir CHARLES RIVERS WILSON, G.C.M.G., C.B. There was a leaven of electrical men, including several well-known consultants, manufacturers and trolley tramway engineers; but there were also present many tramway men to whom the trolley wire is as yet an unfamiliar thing. Ere long the little leaven shall have leavened the whole lump. We wish the association every success, and rejoice that it has been promised already the hearty co-operation of the Institution of Electrical Engineers in safeguarding the interests of electric traction. In the newly-formed association we perceive the embryo of what should become a powerful and useful public body.

WITH regard to the question of overhead wayleaves for telephone wires on the Bedford Estate, referred to in our last issue, we learn that the matter is even more serious than might appear at first sight. We are able to state that it is no exaggeration on the part of the National Telephone Co. to describe the payments demanded by the ground landlord as prohibitive, and if the two parties to the dispute cannot come to terms the result may be a serious diminution of telephonic facilities in the metropolis. The Bedford Estate covers a small but important district to the north of the Strand, including one or two theatres (whose loss on being deprived of their telephones will not be slight) and several publishing houses and other business premises; and north of Oxford-street, the residents in Russell-square, Tavistock-square, Gordon-square, Woburn-square, Great Russell-street and part of Gower-street are tenants of the DUKE OF BEDFORD. In fact, from 700 to 1,000 subscribers are directly interested in the dispute, and, in addition, considerable alterations may be necessitated in the lines of other subscribers which pass over the estate on their way to the exchange, as a similar payment for wayleave is also demanded on these. The simplest and most reasonable solution of the way-leave difficulty would be for the Post Office, the Corporation of London, the London County Council, and the National Telephone Co. to arrive at an agreement permitting the latter to lay underground wires. The only result of the destruction of the company's business, so far as the Post Office is concerned, would be the loss of an important source of revenue to that department, for the sums received as telephone royalties go far towards diminishing the telegraph deficit; and as to the other authorities, in hampering the company's operations, they are doing their best to prevent that fair competition they profess to be so anxious to secure. In any case, the campaign against the company has been commenced too soon, for the Post Office telephone

(RECAP)

Digitized by Google

system is not yet in operation; and those who are now deprived of the National Telephone Co.'s service will be entirely without telephonic communication of any sort for some months at least.

If any individual, hard to please or otherwise, was disappointed in Sir William Preece's "James Forrest" lecture on Monday last, he certainly must have felt abundantly compensated by the impromptu word-battle between the lecturer and Sir Frederick Bramwell, which took place after the discourse was over. Sir Frederick, in a smart little speech seconding the vote of thanks, uttered his well-known formula that "he was tired of hearing it said" that this country was behind the world in electrical engineering. The blame for this tardy progress lay not with engineers, but with those who had passed "a facetious Act of Parliament, in 1882, styled—he believed—an Act for the Encouragement of Electrical Enterprise."

The evil in this Act chiefly lay in the clause permitting a local authority to compel the sale of any electrical undertaking after 21 years, at a price which should take no account of past or future profits. He had described this Act to American engineers, when he was in the United States, and had been laughed at for his pains—it was perfectly incredible to them that such an insane Act could exist in any civilised country. Nor did the Act of 1888 much improve matters; it only extended to 42 years the period that might elapse before the local authority could seize the undertaking. To these caustic strictures upon our electric lighting legislation, Sir William Preece retorted that Sir Frederick was utterly wrong; no better Act than the Electric Lighting Act (1882) was ever passed. Sir William did not say why; and his *ipse dixit* made the audience titter without convincing it. He went on to say that the Act was modelled upon the Tramways Act (1870), which had the same "21 years' purchase" clause. And if ever a tramway company and a local authority were in dispute as to this clause, they were sure to appoint Sir Frederick as arbitrator.

Delicious as undoubtedly was the humour of this home thrust at the famous Bramwell decision, it was hardly fair to Sir Frederick. When acting as arbitrator on a matter connected with the 21 years' purchase clause, he is not called upon to decide whether that clause is iniquitous or radiantly beneficent; his plain and simple duty is to interpret the text of the clause as it stands. It is ludicrous therefore to blame Sir Frederick Bramwell for the unjust conditions of the Tramways Act (1870), because, forsooth, he will not close his professional eyes to their clear and undoubted meaning. No one, we venture to think, would more heartily concur in the abolition of these purchase-clause conditions than would Sir Frederick himself.

Mr. Campbell Swinton's article on "Electrical Conductors and Dirt," in another column of this issue, offers a fresh reason for the householder to insist upon the switches for his electric lamps being placed in the proper position. Mr. Swinton has found, by observation in his own office, that "flexible," charged to a potential of 200 volts, will attract dust to a greater extent than when it is at a lower or at zero potential. Most modern supply networks are now on the three-wire system with the neutral wire earthed; consequently, if switch lamp holders are eschewed and the switches placed before the flexible cord (*i.e.*, to the station side of it) and on the outer (unearthed) wire, as they should be, all parts of the cord remain at zero potential until the lamp is switched on, and resume this value as soon as it is switched off again. Mr. Swinton's suggestion that, on systems not intentionally earthed, all single-pole switches should be placed on the more positive of the two wires, owing to the greater surface leakage on the negative conductor, is also an excellent recommendation. It is not new, however, for it was suggested in our correspondence columns five years ago.

The Royal Society of Victoria.—Prof. Kernot has been elected president of the Royal Society of Victoria.

Institution of Electrical Engineers Conversazione.—We are officially informed that the annual conversazione will this year be held on Tuesday, June 26th, in the Natural History Museum, South Kensington.

The Institution of Mechanical Engineers.—The annual dinner, which was arranged to take place on April 25, has been postponed to Wednesday, June 27, when it will form part of the summer meeting.

South Western Polytechnic.—A university extension course of five lectures on "The Direct Current Motor" is to be given by Prof. C. A. Carus-Wilson, M.A., on Mondays at 8.30 p.m, commencing May 7.

The Zipernowski-Déri Patent.—Among the forthcoming legal actions set out elsewhere, it will be seen that Mr. Rücker is appealing against Mr. Justice Farwell's judgment in the case of Rücker *v.* London Electric Supply Corporation (Ltd.).

An American Physical Laboratory Burnt Down.—The physical laboratory of Lehigh University, Pa., one of the largest and best equipped in the United States, was burned to the ground on the 6th inst., and all its scientific apparatus destroyed. The loss is estimated at $200,000.

Personal.—Major R. E. B. Crompton, of the Electrical Engineers (R.E.) Volunteers, has been granted the temporary rank of Major in the army while serving with the volunteers section in South Africa. Second-lieutenants H. F. Bigge and F. P. Williams, also of the Electrical Engineers, have been appointed temporary Second-lieutenants in the army under similar conditions.

Cable Interruptions:—	Date of Interruption.
Latakia—Cyprus	June 21, 1899
Cayenne—Pinhieros	Oct. 11, 1899
Tangier—Tarifa	Jan. 3, 1900
Paramaribo—Cayenne	Feb. 16, 1900
Ceara—Maranham	Feb. 20, 1900
Para—Maranham	Mar. 2, 1900
Môle St. Nicolas—Cap Haitien	Mar. 7, 1900
Trinidad—Demerara	Mar. 30, 1900
Manila—Iloilo	April 9, 1900

Industrial Progress in Siam.—The American Consul-General stationed at Bangkok, in a communication to his Government on the industrial development of Siam states that most of the rice and teak mills in the country are equipped with electric light plants. All but one of these plants were furnished by English firms. He suggests that street transportation in Bangkok offers opportunities for the introduction of light-running vehicles. The workmanship and material must be of unexceptionable quality to meet the climate, which changes very quickly from extremely wet to hot and dry.

Iron and Steel Institute.—The annual meeting of the Institute will be held at the Institution of Civil Engineers, Great George-street, Westminster, on Wednesday and Thursday, May 9 and 10, commencing each day at 10.30 a.m. Among the Papers down for reading are: "The Manufacture and Application of Water-Gas," by Carl Dellwik (Stockholm);

Digitized by Google

"The Solution Theory of Iron," by Baron H. von Jüptner (Donawitz, Austria); and "Iron and Phosphorus," by J. E. Stead, F.I.C. (Middlesbrough). Members who desire to participate in the discussion can have copies of Papers forwarded a week in advance. Visitors can also obtain tickets on application.

Municipal Electric Supply in Vienna.—The city of Vienna, which has hitherto been supplied with electricity by a company, is now to have its own municipal station, and the contract for building this has been awarded to the Austrian Schuckert Co., which is also to build a power station for the municipal electric tramways. The latter will contain five units of 3,000 H.P each and the former three units of similar size, with room for extensions embracing three and one more unit respectively. The tramway station is to be running by the middle of the year 1901, and to be completed by the end of that year; and the station for general supply should also be completed by then or soon after. A loan of £1,250,000 is to be obtained for the purpose.

German Patents Statistics.—During the year 1899 21,080 patents were applied for, compared with 20,080 in 1898 and 18,347 in 1897. Of these 7,430 were awarded after examination by the Patent Office, the corresponding number during last year having been 5,570. Thus, while the number of applications only increased by 3·7 per cent., the number of successful applications increased by 33·4 per cent. During the year, 5,171 patents have expired or become void, and the total number of patents in force is 22,198. The increase in the number of patents awarded is chiefly marked in the case of electrical apparatus and machinery. 265 patents were awarded in this class in 1898, and 439 in 1899. Patents granted to foreigners are also on the increase. United States leads the way with 722, England follows with 554, France 474, Austria-Hungary 372, Sweden and Norway 99, and Russia 85.

Eighty-Mile Electrical Transmission in Canada.—The *Electrical World and Engineer*, of New York, states that the works of the Showinigan Water and Power Co., by means of which the power developed from the Showinigan Falls will be transmitted to Montreal, a distance of 80 miles, will shortly be completed. These works consist of a canal and the necessary flumes, &c., for developing 30,000 H.P., which can be readily increased to 75,000 H.P. if required. The line will run along the Great Northern Railway to Jolliette; thence to the island of Montreal by an aerial line, and into the city. By reason of the low cost of generation at the Falls, and the studied economy in transmission, it is anticipated that the company will be able to deliver power in Montreal at very moderate prices. Initially only 5,000 H.P. will be delivered, which will be increased as required.

International Tramways Congress.—It is announced that an international congress on tramways will be held in Paris from Sept. 10 to 13, under the auspices of the Permanent International Union of Tramways. Particulars may be obtained from the general secretary (Mr. F. Nonnenberg), 85, Rue Potagère, Brussels, or from the secretaries of the Paris International Assembly, 5, Henrietta-street, W.C. The congress will include in its programme the questions of heating of carriages, brakes, electrical traction, &c., and proposes to go thoroughly into the question of tariffs. Of the 272 tramway companies—or officials—who constitute the ordinary members of the union, it is stated that not one is British, while Turkey is represented, and even the Philippine Islands contribute one member. Among the 140 extraordinary members, other than tramway companies, there are only five British engineering firms!

Wireless Telegraphy.—Various accounts have been circulated as to the cause of the removal of the wireless telegraph installation between the South Foreland lighthouse and the Goodwin lightship. As a fact, the installation was erected over a year ago chiefly for purposes of demonstration, and it can justly be claimed that it has proved the practical utility of the Hertzian system for signalling to lighthouses and lightships. As it appears that the Trinity House authorities had no funds at their disposal to purchase the instruments, and Marconi's Wireless Telegraph Co. requires the services of its assistants elsewhere, the company removed the installation a few weeks ago. Some assistants are being sent out to Honolulu to erect instruments for communicating between the islands of the Sandwich Islands group. The American company recently formed has, we are informed, no connection with Marconi's Wireless Telegraph Co., which still owns Mr. Marconi's American patents.

Obituary.—We regret to announce the death of Sir Francis Marindin, K.C.M.G., which took place on Saturday last at 3, Hans-crescent, S.W. The deceased, who was at the time of his death 62 years of age, was well known to our readers as an inspector, on behalf of the Board of Trade, of railways and tramways, including of course those worked electrically. His name will also be remembered in connection with the inquiries conducted in the early days with regard to the development of electric lighting companies in London. He entered the Royal Engineers in 1854, and saw service in Mauritius and Madagascar, and obtained the rank of Major before retiring in 1874 from a staff appointment which he held at the Chatham School of Military Engineering. In 1877 he joined the Board of Trade as Inspector of Railways, in which capacity he did much useful work by his strong and impartial criticism of railway management, more particularly in connection with overworked employés. Major Marindin obtained his C.M.G. in recognition of his services in connection with the Egyptian State Railways, and on the occasion of the Diamond Jubilee he was made a Knight of that Order.

Nominations for the New Council of the Inst.E.E.—The following is a list of the Council nominations for the election of Council and hon. officers for 1900-1901, as announced at the ordinary general meeting yesterday:—

President.
Prof. J. PERRY, F.R.S.

Vice-Presidents.
Mr. W. E. Langdon. | Mr. R. K. Gray.
Mr. James Swinburne. | *Mons. E. Mascart.

Members of Council.

Major P. Cardew, R.E.	Mr. Robert Hammond.	*Mr. C. P. Sparks.
*Mr. H. H. Cunynghame, C.B.	*Mr. Hugo Hirst.	Mr. A. A. Campbell Swinton.
	Mr. A. J. Lawson.	
*Mr. H. Edmunds.	Mr. P. V. Luke, C.I.E.	*Mr. A. P. Trotter.
*Mr. S. Z. de Ferranti.	Mr. W. M. Mordey.	*Mr. J. E. Kingsbury.
Mr. John Gavey.	Mr. R. P. Sellon.	

Associate Members of Council.
*Mr. W. R. Cooper, M.A., B.Sc. | Mr. S. Evershed.
Mr. R. W. Wallace, Q.C.

Honorary Auditors.
Mr. F. C. Danvers. | Mr. E. Garcke.

Honorary Treasurer.
Prof. W. E. Ayrton, F.R.S.

Honorary Solicitors.
Messrs. Wilson, Bristows and Carpmael.

The names marked with an asterisk are those of gentlemen nominated to fill the vacancies in the council in accordance with Article 45 of the articles of association. All the honorary officers being eligible are nominated for re-election.

The Institution of Civil Engineers.—At the annual meeting of the Institution of Civil Engineers, held on Tuesday evening, Sir Douglas Fox, president, in the chair, the result of the ballot for the election of officers was declared as follows:—President, Mr. James Mansergh; Vice-Presidents, Sir William White, K.C.B., Mr. Charles Hawksley, Mr. J. C. Hawkshaw, M.A., and Mr. F. W. Webb; other Members of Council, Mr. Barton (Dundalk), Mr. Horace Bell, Sir Alexander Binnie, Mr. B. Hall Blyth, M.A. (Edinburgh), Dr. Henry Taylor Bovey, M.A. (Montreal), Mr. C. A. Brereton, Mr. T. Forster Brown (Cardiff), Mr. R. Elliott Cooper, Mr. G. F. Deacon, Mr. W. R. Galbraith, Mr. G. H. Hill, Mr. J. C. Inglis, Mr. Alexander Izat, C.I.E. (Gorakhpur, India), Dr. Alexander B. W. Kennedy, Sir James Kitson, Bart., M.P. (Leeds), Mr. A. G. Lyster (Liverpool), Mr. John Allen McDonald (Derby), Mr. E. Pritchard Martin (Dowlais), Mr. William Matthews, Sir Guildford L. Molesworth, K.C.I.E., Mr. Alexander Siemens, Mr. Thomas Stewart (Cape Town), Mr. John I. Thornycroft, Mr. William Thwaites, M.A. (Melbourne), Prof. W. C. Unwin, B.Sc., and Sir E. Leader Williams (Manchester). The Council have made the following awards for Papers read and

Digitized by Google

discussed before the Institution during the past session:—a George Stephenson medal and a Telford premium to Sir Lowthian Bell, Bart., LL.D., F.R.S.; Telford medals and premiums to Messrs. H. H. Dalrymple-Hay, B. M. Jenkin, F. W. Bidder, and F. D. Fox; a Watt medal and a Telford premium to Mr. J. Dewrance; a Crampton prize to Sir Charles Hartley; and Telford premiums to Messrs. C. N. Russell and R. A. Tatton. The presentation of these awards, together with those for Papers which have not been subject to discussion and will be announced later, will take place at the inaugural meeting of next session.

May's Fire Annunciator.—A simple form of fire annunciator, devised by Mr. C. E. May, electrician to the New Zealand Government, is being introduced by the May-Oatway Syndicate. A copper wire of about 18 gauge and 20ft. in length is stretched on the wall of each room of the house in which the annunciator system is installed. To the centre of this wire a small carbon-tipped weight is suspended, and when the temperature of the room rises above a certain value, the sag of the wire causes the weight to come in contact with a platinum point, and thus close the circuit of a bell and indicator. The distance of this point from the carbon-tipped weight is adjustable, so that the annunciator can be brought into action for any required rise of temperature; $\frac{1}{32}$in. between the contacts is allowed per degree Fahrenheit. For houses within reach of the fire brigade, it is proposed to place the indicator on the front of the house, and to connect it with an automatic Morse transmitter. This latter is so arranged that an electromagnet is energised as soon as one of the crude thermostats mentioned above comes into operation, a magnet pulling over the starting lever of a train of clockwork. This turns a disc on which are projections to operate the Morse key and make the signal agreed upon by the fire brigade for that particular house. After the disc has revolved once, repeating the signal three times, a catch falls by gravity into a slot in one of the wheels of the train and stops further signals. For the purpose of testing the system, a spring is arranged by means of which the stretched wire can be momentarily loosened, allowing the weight and platinum point to come into contact, and a key is provided so that the wire to the fire brigade station can be switched off when testing. A guard for the stretched wire is also provided when deemed necessary.

Automatic Fault-Signalling on High-Pressure Networks.—The system of the automatic signalling of faults by means of test wires, which has been employed in Berlin (see *The Electrician*, Vol. XXXI., p. 103, Vol. XXXVII., p. 788, and Vol. XXXVIII., p. 51), has been modified to render it suitable for the high-pressure mains in Vienna, the modification being described by Herr Franz Probst in the *Zeitschrift für Elektrotechnik* of April 1st. In the Agthe system, employed in Berlin, the + pilot wire is laid up with the − cable, and the − pilot wire with the + cable, these wires being connected to their voltmeters through indicating relays, so that a fault is signalled by a bell as soon as it occurs, and its position is notified by the number of the indicator which has fallen. This method as it stands is obviously unsuitable for high-pressure cables, as it would be impracticable to lay up with the conductor a wire differing from it in potential by a couple of thousand volts. The difficulty is overcome by taking advantage of the low potential of the outer conductor of the concentric system, and laying two test wires insulated with impregnated fibre among the wires forming this conductor. The station ends of these test wires are connected through resistances and indicators to one terminal of the 100-volt winding of a transformer, the other end of this winding being earthed and the primary being connected to the 2,000 volt station 'bus bars. If the cable is injured externally, one of the test wires will get connected to earth, or, what is equivalent, to the outer conductor; and a circuit is thus established and the indicator drops, at the same time closing a local bell circuit. One of the two test wires is also connected in such a way that it signals the intrusion of water into junction boxes. It is stated that the system, which has been tried experimentally by the International Electricity Co. of Vienna, has given such satisfaction that it is to be extended to all the cables containing test wires.

The Formation of Planté Plates.—The original Planté process, by which it took two months to form the plates, gave very excellent results so far as the durability of the plates was concerned, but the time required was too long for practical purposes. Accordingly various methods were tried to expedite the formation of a sufficiently thick layer of active material on the surface of the plates, which consisted principally in rubbing into them a paste composed of one of the oxides of lead, or of employing a forming bath which contained a small percentage of chlorine or perchloric acid, or some other substance which would eat into the lead. But it was soon found that the impurities which the oxides of lead usually contain were very injurious to the life of the plates, and that unless the latter could be thoroughly freed from the solution used in the forming bath, this continued to eat into them after the cells had been formed and were at work. The fact that the formation process is thus continuing is shown by the increase in the capacity of the cell, and when this increase is rapid, it means that the life of the plates will be correspondingly short. Many attempts, therefore, have been made to find a bath which would hasten formation, whilst at the same time its action would not be continued after the plates had been removed from it and been set up in the working cells. Dr. H. Beckmann, in the *Centralblatt für Accumulatoren und Elementenkunde* states that he has been carrying out an extended series of experiments on the subject, and finds that an aqueous solution of sulphurous acid gives very good results if it is used as soon as it is prepared, and before the sulphurous acid has had time to oxidise to sulphuric, in which case the amount of peroxide formed is very small. The formation of peroxide of lead takes place readily in the presence of sulphurous acid, and in 23 to 24 hours the requisite capacity can be obtained, and it is claimed for this process that little or no subsequent increase of capacity takes place, since no substance injurious to the life of the plates is employed.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

(TO-DAY) FRIDAY, April 27th.

PHYSICAL SOCIETY.

8 p.m. Ordinary Meeting in the Solar Physics Observatory, Exhibition-road, South Kensington. Agenda: (1) A Short Account of the Physical Problems now being investigated at the Solar Physics Observatory and their Astronomical Applications, by Sir J. Norman Lockyer, F.R.S.; (2) Weather permitting, the 36in., 10in., and 9in. telescopes will be used for the observation and photography of celestial objects and their spectra. The Appu-Spottiswood coil and 21ft. Rowland grating will also be in operation.

ROYAL INSTITUTION.

9 p.m. Evening Discourse by the Rt. Hon. Lord Kelvin, F.R.S., on "Nineteenth Century Clouds over the Dynamical Theory of Heat and Light."

THURSDAY, May 3rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture II.: "A Century of Chemistry in the Royal Institution," by Prof. J. Dewar, F.R.S.

RÖNTGEN SOCIETY.

8 p.m. Exhibition evening at 20, Hanover-square. The following demonstrations will be given: (1) A New Method of Localisation without Plumb-lines or Threads, by Prof. F. R. Barrell: (2) On a Form of Focus-tube Designed to be Self-heating, by Dr. Dellpratt Harris; (3) A New X-Ray Film—"Cristoid," by C. Williams. Mr. M. Davidson will show, if possible, the Stereoscopic Fluoroscope. Exhibits as follows have been promised: Mr. Bowron: (*a*) A portable 8in. Spark Coil with improved Break; (*b*) A semi-portable 15in. Spark Coil with improved Break; (*c*) A Milliampèrimeter, for measuring the Secondary Discharge of Induction Coils. Mr. J. H. Gardiner: Skiagrams of British Reptiles, &c. Mr. Isenthal: Jet Mercury Break, &c. Dr. F. H. Low: A portable 10in. Coil, &c. Messrs. Parsons and Eachus: A Portable 8in. Set. Mr. E. H. W. Shenton: Skiagrams, Localiser Couch. Mr. Wimshurst: Influence Machine with Vulcanite Plates.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting at the Institution of Mechanical Engineers, Storey's-gate, S.W. Paper to be read: "The Calculations of Distributing Systems of Electric Traction under British Conditions," by H. M. Sayers. To be preceded, if necessary, by the conclusion of the discussion on Prof. Forbes' Paper, read on April 26th.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Identity of Radium and Cathode Rays.—H. Becquerel has made a discovery which appears to decide the nature of one kind of Becquerel rays, at all events, those called "radium rays" by Curie. These, according to Curie's experiments, transport an electric charge, a fact which already points out a close analogy with cathode rays. The analogy would be made perfect if it could be shown that radium rays were subject to electrostatic as well as magnetic deflection. This has been done by Becquerel, though not without encountering serious difficulties owing to the feebleness of the sources available and the consequent smallness of the deflection to be observed. He succeeded in proving photographically, by means of an electric field of a billion units, that the rays or particles proceed in a parabola having the vector of the electric field for its axis. Their velocity is something between half and two-thirds of that of light. On comparing the magnetic deflection of a beam with its electric deflection, the ratio e/m is found to be about 10,000,000, or the ratio of an infra-red vibration of the Zeeman ions. The energy expended is a few C.G.S. units per second, or a few ten-millionths of a volt. This would mean a loss of matter of about 1 milligramme in 1,000 million years. This explains the inappreciable loss of matter actually found.

[H. Becquerel, *Comptes Rendus*, March 26, 1900.]

Dissociation Theory of the Arc.—By photographing a narrow longitudinal section of an alternate-current arc on a long moving film, Brown showed that the arc is formed by the coalescence of two light-fronts, starting from the positive and negative carbons respectively. The negative light-front starts first, but the positive one moves with the greater velocity. The former circumstance is easily explained, as the negative carbon was positive during the previous half-period, and was therefore the hotter of the two. As regards the difference of velocity, it is difficult to account for it without having recourse to some ionic hypothesis. Such an hypothesis has been framed by C. D. Child, who supposes that the negative ions move more slowly than the positive ions. This is the reverse of what happens in the case of dissociation by Röntgen rays. The greater velocity of the positive ions would not only explain the fact observed by Brown, but also the greater fall of potential at the positive pole. Manometric experiments show that the pressure near the positive carbon is greater than that near the negative carbon. The author explains this on the ground that owing to the smaller speed of the negative ions their number between the poles at any given time must exceed the number of the positive ions. Hence they exert a greater attraction upon the positive pole than do the positive ions upon the negative pole.

[C. D. Child, *Phys. Review*, March, 1900.]

Electrolytic Convection in Vacuum Tubes.—J. J. Thomson does not think that Morris-Airey's experiment (see *The Electrician*, May 16, p. 732) disposes of his theory of electrolytic convection in vacuum tubes. That chlorine should be found in all parts of the tube is inevitable when as large amounts of chlorine are mixed with the hydrogen as in Morris-Airey's experiments. For the increase of the partial pressure of the chlorine must accelerate its diffusion throughout the tube. In Thomson's original experiment a very small quantity of chlorine was mixed with the hydrogen, and the effects observed were not merely the presence of the chlorine lines at the anode and their absence at the cathode when the current was steady, but it was found that on reversing the current, so that the old anode became the cathode, the chlorine lines at first flashed out brightly at the new *cathode* and were faint at the anode. Then there was a short interval during which they were faint at both electrodes, and finally they became bright at the new anode and invisible at the cathode. This seems a very complete proof of the transport of chlorine to the anode, and of the electrolysis of gases in a vacuum tube.

[J. J. Thomson, *Phil. Mag.*, April, 1900.]

Change of Volume by Magnetisation.—There is still a popular impression, based upon the results of Joule's experiments, that the volume of a magnetic substance does not change on magnetisation, though its length does. Cantone found that this is not strictly true, and H. Nagaoka and K. Honda have therefore studied the behaviour of iron, steel, and nickel ovoids in this respect. They found that a change of volume becomes very apparent when stronger fields are used. They used a field-strength of some 2,200 units. Iron and steel ovoids, they found, show a considerable increase in the volume change on annealing. Tungsten steel is not affected by annealing, but the volume change, or increase of volume on magnetisation, is twice as great as it is in soft iron, being 2·5 millionths at 1,400 units of field strength. As regards the effect of torsion, the transient current, as well as the longitudinal magnetisation produced by twisting an iron or steel wire, is opposite to that of nickel in moderate fields; it reaches a maximum in weak fields; but in strong fields the direction of the current as well as the longitudinal magnetisation is the same in iron, steel, and nickel.

[Nagaoka and Honda, *Phil. Mag.*, April, 1900.]

The Echelon Spectroscope.—A valuable addition to our instrumental resources for observing the Zeeman effect is the "echelon" spectroscope invented by Michelson two years ago. Its principle, it will be remembered, is radically different from both the prism and the grating. It is made up of a number of glass plates of graduated sizes, each a little shorter than the previous one, and built up in the form of a pyramid, the base of which is turned towards the source, while the summit is turned towards the observer's telescope. Lord Blythswood and W. E. Marchant have constructed a spectroscope of this kind with an echelon of fifteen flint-glass plates each about 7·5 mm. thick, set with steps 0·5 mm. wide. It was found that the yellow and green mercury lines were far easier to examine than the blue, on account of the diminution of the dispersive power of the instrument for the shorter wave-lengths. To obviate this drawback the plates should be made thinner and more numerous, Otherwise the working of the instrument is highly satisfactory, while its cost is, of course, very considerably below that of a grating of equal resolving power. The ratio e/m for the mercury lines varied from $28{\cdot}0 \times 10^6$ at $\lambda = 4{,}358$ to $17{\cdot}2 \times 10^6$ at $\lambda = 5{,}790$ A.U.

[Blythswood and Marchant, *Phil. Mag.*, April, 1900.]

The Electric Light in Photo-Micrography.—In many branches of photography the electric light has been found to yield results frequently more satisfactory than those obtained by ordinary sunlight. One of the most recent and most effective applications is in connection with photo-micrography, and is described in the *Electrical Review* of New York. An automatic focussing arc lamp is placed in a nearly horizontal position, so that most of the light given will be projected vertically upwards, passing through a condensing lens and the object to be photographed, to the sensitive plate. The lamp gives 2,000 c.p., and, by varying the resistance, it can be made to furnish 5,000 c.p., or even more; and for work upon living organisms, magnified as high as 200 diameters, an exposure of $\frac{1}{40}$th of a second has given good results. In the work for which this lamp is used the light passes through the condensing lens and thence to the microscope stationed directly above. The object which is to be photographed, if a living specimen, is placed in a drop of water upon a piece of thin clear glass and the light turned on. A special shutter containing a total reflecting prism is placed in such a position that no light can pass to the sensitive plate which is all the time exposed inside the camera bellows, but after passing through the microscope is turned upon a ground-glass screen at the end of a conical view tube, which enables the operator easily to study the movements of the specimen. When it assumes the desired position, a pneumatic release allows a spring instantly to remove the prism from its first position and the light passes through an opening in the shutter to the plate.

THE ELECTRICAL EQUIPMENT OF THE ELECTRICAL ENGINEERS (R.E.) VOLUNTEER CORPS.

As we have already announced, 58 men and six officers of the Corps of Electrical Engineers (R.E.) Volunteers sailed for South Africa on March 16th, under the command of Capt. Lloyd, R.E., and took with them two complete search light trains, each consisting of two search lights, two waggons, and one traction engine, each traction engine being fitted with its own dynamo. In addition to this a spare dynamo was taken, as well as 24 arc lamps with portable lanterns, and 200 incandescent lamps. A number of cycles, some of which were fitted with special cable-laying drums, were taken out to work in connection with the field telephones, and to facilitate communication in general. On April 14, Major Crompton, together with a second contingent of about ten men, sailed for South Africa, taking with them a third traction engine. In all probability, this third engine will join the first contingent, as we understand that Major Crompton himself has received instructions to proceed independently of his corps to the very front, with a view of discussing with Field-Marshal Lord Roberts certain problems relating to electricity in the field, as well as to the question of transports generally in South Africa.

Major Crompton has submitted to the War Office a scheme for working the transport service of an entire division of the army, independently of all railways, and it is in connection with this that he has received instructions to proceed to the front and explain personally the problems connected with it. We understand that the general principles of the scheme have been favourably criticised by the War Office authorities, and knowing the special study which Major Crompton has made of traction engines—for he was, in fact, actively engaged for nine years in experimenting on road traction for the Indian Government, long before he thought of electricity—we feel that the War Office could not obtain the services of a better man.

The plant taken out by the corps is described further on, and, in passing, attention might be drawn to the fact that an equipment of this description is quite novel, the field search light hitherto consisting of an ordinary ship search light mounted usually on railway trucks, a combination which is quite unsuitable for work in active warfare. Major Crompton has consequently had no light task in getting this equipment designed and assembled in the short period available, as everyone is aware of the difficulties of obtaining material at the present time with reasonable deliveries. The plant which has already arrived in South Africa can be used for various purposes, and where one application is not suitable another will no doubt be found. The traction engines can be used for ordinary transport purposes, or they can be used for driving the dynamos either for working the search lights or for running a motor. The search lights will find use either for signalling or for reconnoitring purposes. The possibility of being able to lay telephone wire at the rate of eight to 15 miles per hour is likely to be of importance, and one can confidently expect that considerable use will be made of a portion of the present corps in facilitating the difficult problem of keeping adequate communication between various points by this means.

Traction Engines.—In Fig. 1 is shown the type of traction engine which has gone out. An engine to perform the various duties required of it, as in the present case, is not an easy thing to find, yet these, built by Messrs. C. Burrell & Sons, of Thetford, seemed very suitable for the work. They are light, weighing between eight to nine tons, whilst indicating 18 H.P. In fuel consumption they are reasonable, consuming under ordinary conditions of working between six and eight cwt. of coal per eight-hours day. They are of single crank compound type, the two cylinders being arranged one above the other, whilst the two piston rods work on a single crosshead, to the centre of which the connecting rod is attached. The engines are arranged to carry a load of 12 ton each, and it was found that on an average road they could travel for six miles with the water carried on the locomotive. It was expected after the sappers had got used to the handlines of the engines that the water consumption would be somewhat reduced.

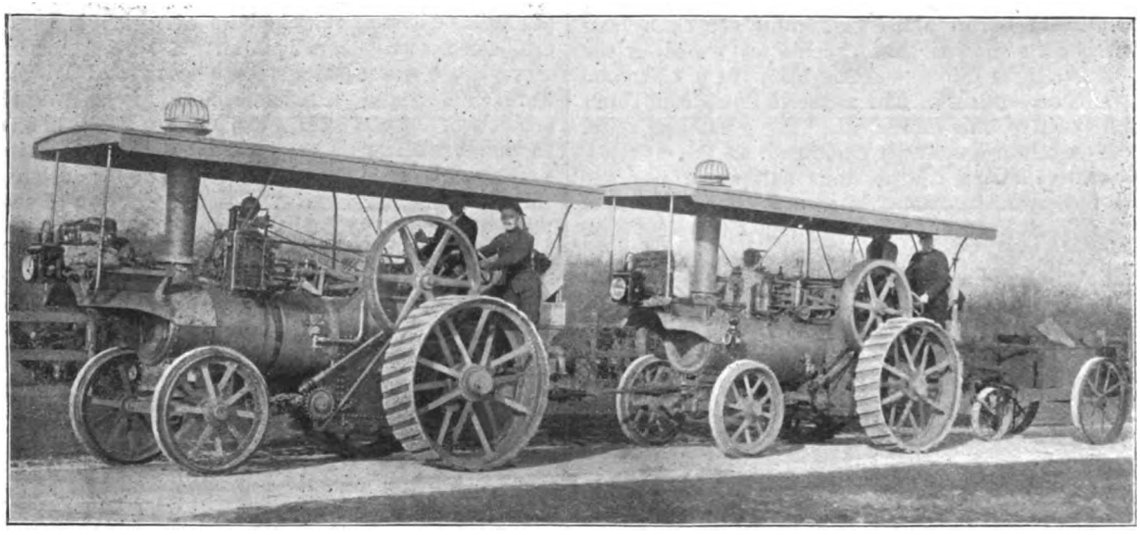

FIG. 1.—TRACTION ENGINES FOR THE WAR IN SOUTH AFRICA.

When driving the dynamos about 32lb. of water per hour per electrical horse power developed was consumed, though this would in all probability be reduced to 28lb. when in thorough working order. Water consumption is one of the most important items for traction engines in South Africa, and with a view of still further economising this, the third engine has been fitted with partial condensation. It was intended that one waggon per traction engine should be used exclusively for carrying additional water and coal, to minimise the number of stops necessary for these purposes. The dynamos, although not shown in Fig. 1, were fitted up on the bracket provided in front of the engine. In the illustration this space has been occupied by the sappers' luggage.

The dynamos are of the multipolar semi-enclosed type, manufactured by Messrs. Laurence, Scott and Co. and Messrs. D. Bruce Peebles & Co., being designed for an output of 110 volts and 80 to 100 amperes at 750 revs. By using 110 volts, two arc lamps can be run in series, which would of course have been impossible with the standard pressure usually adopted for search-light volts—viz., 80 volts. It was found necessary to fit some special spring arrangements to the front of the engine, to prevent as much as possible the jolts from being transmitted to the dynamos. The dynamos are belt driven off the engine flywheel. Finally, as shown in Fig. 1, the

Digitized by Google

engines are completely roofed over, and by means of waterproof blinds dropped from the top, but not shown in the illustration, they can be completely covered in.

Search Lights.—The details in connection with these have had to be specially designed. Fig. 2 shows the general arrangement of the search light plant, on the left hand side being the projector mounted on its trail, whilst on the right hand side is the limber belonging to the search light. The gun metal bases of the search lights are arranged to revolve on balls over turntables, and a degree circle is fixed in the centre with a moveable pointer to facilitate getting the search lights into line should a number be used for reconnoitring purposes. The object of the dial and moveable pointer is to facilitate the working of a number of projectors at a distance by means of commands given on a telephone. It will be noticed that the trails are similar to gun carriages, but are mounted on springs. The wheels on which these trails were mounted, were made at the Royal Arsenal, which ensures their easy renewal in the field. If it should be required to use the search lights for stationary purposes, they can be detached from their trails and used on the ground, their four feet being each adjustable as to height. Aluminium is used for mounting the mirrors, glasses, and divergers, whilst the reflectors manufactured under Coles's patent are of deposited copper, faced with silver, with a thin coat of palladium to prevent tarnishing. The divergers are manufactured by Messrs. Chance Bros. and Co. Major Crompton has however taken out one of Parsons hyperbola-parabola diverging mirrors. This mirror causes the beam to cross in a narrow slit of light outside the barrel, thus enabling the projector to be totally protected by sandbags or other armouring.

The pattern service lamp was found far too heavy and clumsy for work of this description, and consequently it has been found necessary to entirely remodel the mechanism of the lamp. It was thought also that the arc striking arrangement would have been damaged by the vibration of the moving carbon, when the lamp was being moved about. The new mechanism in the lamp is arranged to lock the moveable carbon holder in position when once the arc has struck, the feeding movement being controlled by a shunt coil acting on the other carbon holder.

Owing to the somewhat higher pressure adopted, a drop of 52 volts can be allowed between the dynamo and search light, and consequently the search lights may be at least a mile from the traction engines. This distance can be increased on emergency by laying two conductors in parallel. The elevating motion of the search light, which is not required to be worked rapidly, is worked by a worm, and is thus self-locking. The horizontal motion, however, used largely for signalling purposes, has to be worked quickly, and is consequently pulled round by hand. Accuracy is not of so great importance in the horizontal as it is in the vertical motion.

Like ordinary field guns, these search lights have draghooks arranged on the end of the axle, and by means of these they can be hauled along by hand. They are usually when travelling attached to their limbers, and the two drawn together. The trail of the search light is fitted with a powerful screw brake, which can be worked from the back when travelling. It is arranged to allow of attaching an ammeter, voltmeter, and main switch, the latter being permanently fixed. The instruments can be attached at either end, whilst the holes for attaching the main switch are also arranged at both ends.

The search light trails have been made by Messrs. Thorneycroft and Co., whilst the design and manufacture of the search light has been undertaken by Messrs. Crompton and Co.

Limbers.—Fig. 2 gives on the right hand a very good view of one of the limbers, which are made up of wooden boxes lined with steel, the underframes being built up of angle iron. They are mounted on springs, whilst the axles and wheels are made interchangeable with those of the search light trail. By using a pole they can be drawn either by mules or traction engines, and by using ropes they can be drawn by hand. A flap door is fitted at the end of these limbers, and by lowering this the inside of the box, which is thoroughly lined with felt, can be got at. Shelves arranged on the inside are made to accommodate two projector lamps, two mounted mirrors, one plain glass, and one diverger. A box is arranged underneath the seat to accommodate carbons, tools, drag ropes, ammeter, and voltmeter. A screw brake is fitted on the driver's seat, which is capable of carrying two persons. On the roof of the limber will be seen a small box, containing the necessary variable resistance, and this can be used either in position or on the ground. This design of resistance, consisting of short lengths of solid wire fixed between asbestos clamps, is specially suitable for rough work of this description, as little risk is run of short circuiting when the wire becomes heated and expands, and is also much stronger to resist vibration. The limbers were made by the Gloucester Railway Carriage and Waggon Co.

FIG. 2.—ONE OF THE SEARCH LIGHT SETS.

Cable Drum Carriages.—Special carriages had to be designed for carrying the cable drums for paying out the cable, and these were made to take three drums, each drum holding about 200 yards of cable. The cable, capable of carrying about 100 amperes, is chiefly concentric, with the outer

Digitized by Google

conductor bare and braided, to prevent its unwinding should it become cut at any point. There were also taken out some special unions for rapidly connecting up this concentric cable in the field.

The fittings, such as ammeter, switch, &c., would be fixed on the earthed conductor, so that any coupling-up necessary could be carried on without fear of shocks. Each drum has a brake fitted to it to prevent its unwinding; after use the cable is wound up by hand. Here, again, it is arranged that the wheels and axles of the cable carriages should be interchangeable with the ones used on the projectors. The drums can be pulled in either direction either by means of a traction engine or by hand. They can also be attached to the back of the search light, so that the mules dragging the search light and limber also do the work of laying the cable.

Telephones.—Several complete sets of telephones have been taken out, and in addition a number of cycles suitable for paying out the wire for these telephones. Six out of the 20 cycles taken out were fitted with spindles over the back wheels, to which two light cable drums were attached, each drum holding nearly two miles of fine bare copper wire. These drums are shown very clearly in Fig. 3, whilst the telephones themselves are carried on the back of the sapper. It was found that by this means the cyclist could lay the wire as fast as he could ride—say 8 to 15 miles per hour.

Fig. 3.—A Field Telephone Bicycle.

To keep the wire from overrunning small brakes without much friction are fitted on the drums. The drums are placed in such a position that the cyclist can stop them by hand when forced to slow down so rapidly that these automatic brakes are not sufficient. To pick up the wire after use a handle is attached to the drum, and the cyclist, wheeling the bicycle forward with one hand, winds with the other. It is possible to pick up the wire at the rate of about four miles per hour. The telephone wire is bare, and it was found that by using the earth as the return, even on wet ground, it was possible to speak up to three to four miles, with the wire trodden into the ground and even broken. The telephone wire, being very light and cheap, would be left on the ground in the event of its becoming damaged. The telephone itself is of the Swedish cavalry pattern, and can be used either for speaking purposes or for signalling in the Morse code by means of the "buzzer." This would only be done where the length of the line was such that distinct speech was impossible.

The telephones are arranged with a third terminal through a condenser, which enables an enemy's wire to be tapped by connecting it to the third terminal. This can be done without in any way interrupting the conversation, and it is thus possible to hear all that is going on.

THE ELECTRICAL EQUIPMENT OF SHIPS OF WAR.*

BY C. E. GROVE.

(*Continued from Vol. XLIV., page 928*).

Electric Lighting.—The first installation of electric lamps on a warship was put in H.M.S. "Inflexible" in 1881. It consisted of a set of arc lamps run in series from a Brush dynamo, with glow lamps arranged 18 in series on the high-tension mains. The arc light has disappeared. Modern war vessels are usually too much subdivided and have too little head room to justify the use of arc lamps, although these are again becoming somewhat common on merchant vessels. The parallel glow lamp system became standard practice almost as soon as it was introduced, and the number of lamps employed has been steadily increasing. Thus, in the battleship "Colossus," fitted in 1884, 350 lights were installed; in the "Blenheim," first-class cruiser, fitted in 1890, 525 lights were installed; the "Majestic" class of battleships, fitted in 1896, carry between 800 and 900 lamps; the "Albion" and her sister battleships of the "Canopus" class, just completing, carry about 950; the "London" and "Duncan" classes of battleships now building will carry from 1,000 to 1,050 lamps; while the first-class cruisers of the "Drake" and "Monmouth" classes now building will carry approximately 1,000.

Fig. 10.—Schedule of Electric Lighting, H.M.S. "Albion."

It is usual to arrange the electric lamps in six circuits, one circuit being exclusively devoted to engine and boiler rooms, one to magazines, one to central citadel, one to the crew spaces forward, one to the cabin spaces aft, and one to the stores and machinery rooms below the belt deck. It is desirable to have separate circuits for those portions of the ship which are protected by armour, rather than to mix up the lighting of protected and unprotected portions, though this is by no means generally done. A schedule showing the arrangement of lamps, fittings, and circuits on H.M.S. "Albion" is given in Fig. 10. In the United States navy the lamps are arranged on two main circuits, known respectively as the "battle" circuit, which includes the lighting of all parts of the ship occupied in action, and the "lighting" circuit, which includes those parts where general illumination is required for ordinary purposes. Feeders running from the switchboards connect to the respective circuit networks through junction boxes. At "general quarters" the ordinary lighting circuits, which include all the exposed lights on the upper decks, are disconnected at the switchboards. This arrangement prevents stray light shining out-board.

Lead-covered cables and wires, first introduced into the Japanese cruiser "Naniwa-Kan," built at Elswick, are universally used in our navy, and the insulation is now vulcanised indiarubber in all cases. For single lamps a pair of 1/16 wires are employed; stranded wires which group the sets of lamps through fuse-boxes up to the circuits

* Paper read before the Institution of Electrical Engineers, April 5th.

Digitized by Google

are universally composed of multiples of single 20-wire, the standard sizes being 7/20, 11/20, 15/20, 30/20, 60/20, 80/20, and 150/20 ; while for dynamos and heavy motor circuits 350/20 and 550/20 are employed. The current density is usually a little below 1,000 amperes per sq. in., which ensures in the lengths dealt with a very moderate voltage drop. The present mode of fixing the wires and cables is to attach battens of teak to the bulkheads and to run the wires side by side along the teak under brass cleats or saddles. Thus all the wires are visible. According to Admiralty specifications, steel battens may be used as an alternative to teak, but they would be much heavier, and the author is not aware of any ships so fitted. The introduction of these teak battens into our navy took place but a few years ago, and the step appears to have been quite a retrograde one. The employment of wood allows of fewer holes being drilled in decks and bulkheads than would be otherwise necessary, but the aggregate cost of the wiring work is considerably enhanced, useless weight is worked into the ship, and the danger of fire increased. The Japanese have in their latest battleships had the cables and wires attached directly to the decks and bulkheads, dispensing with backings, except where necessary for the heaviest runs or as packing to carry heavy runs of the larger cables over obstructions such as flanges of angle-bars, rows of rivet heads, and the like. This makes a very substantial and satisfactory job. The practice in the United States navy very much resembles land practice. Lead-covered wires were employed at one time, but it is said that the quality of the lead and of the insulation was such as to give trouble and to cause them to revert to the old system. In their latest ships they have run braided wires in wood mouldings in cabin spaces, and in iron pipe or conduit in machinery spaces ; while in the crew spaces and in some of the fore and aft runs the wires are supported below the decks on porcelain insulators, and protected by thin iron guard plate put over them. None of these methods appear to be so safe or so thorough as the British Admiralty method of lead-covered cables closely packed together, and visible and accessible throughout their length.

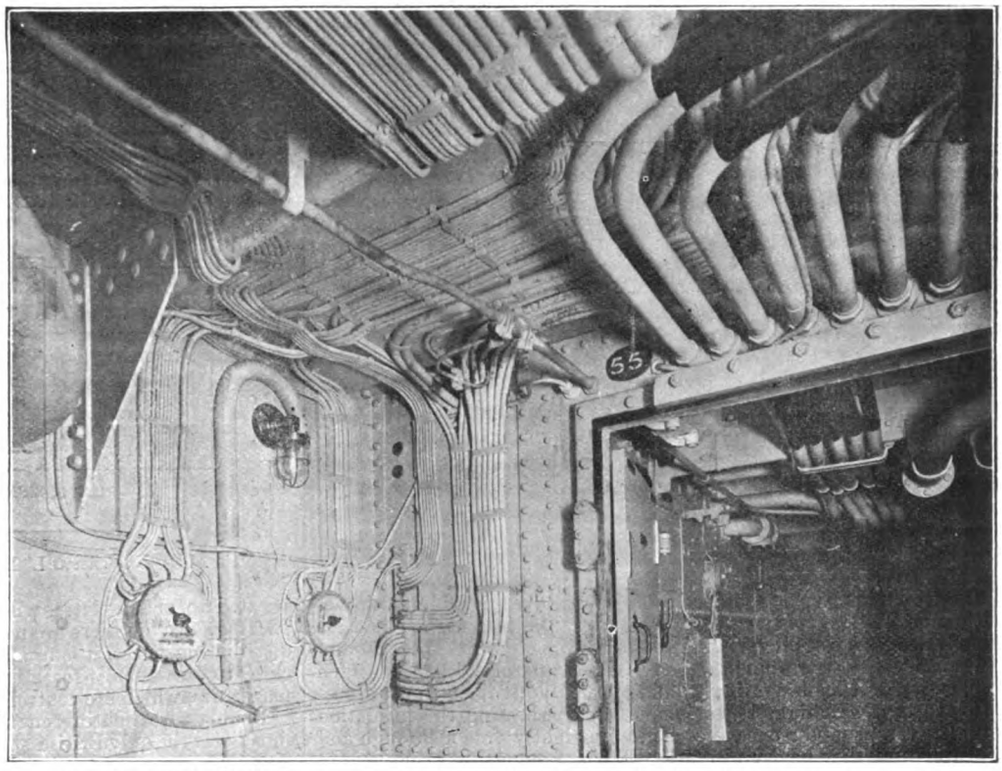

FIG. 11.—Cable Work at entrance to an Ammunition Passage, showing Plate Watertight Glands.

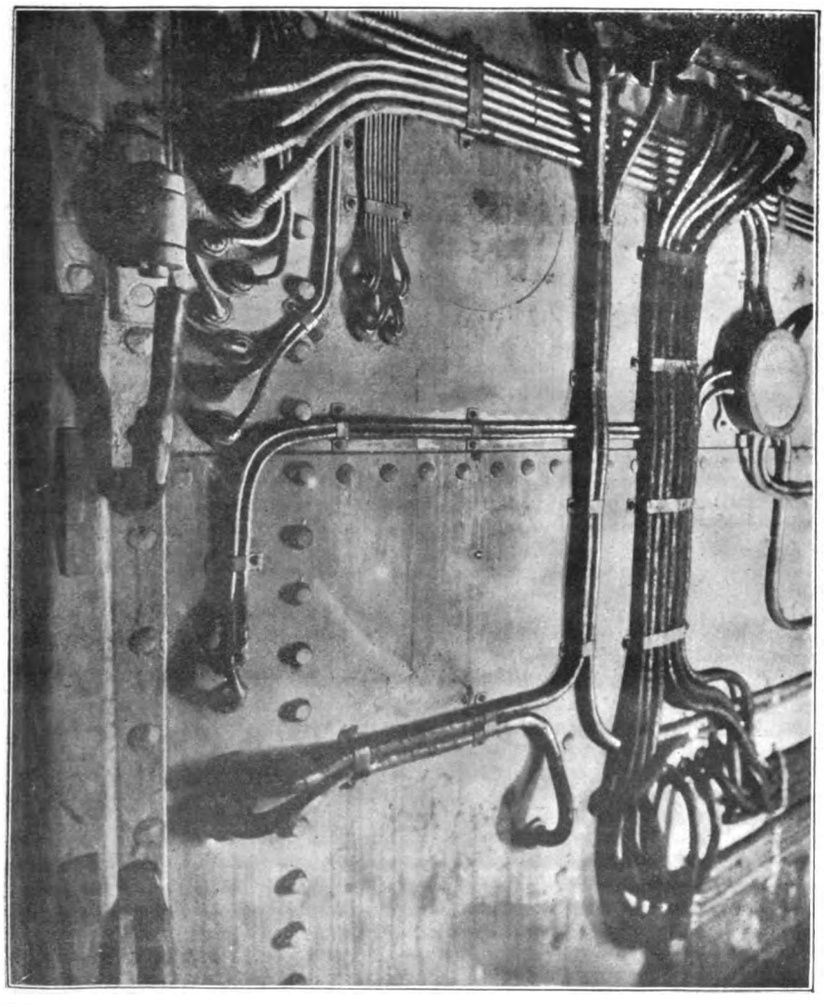

FIG. 11A.—Cable Work behind Switchboard, showing Tubular Watertight Glands.

Watertight Work.—Where the wires go through watertight bulkheads or decks, of course the bulkheads and decks must be made watertight behind them. Until recently the method of making the cables watertight at the decks consisted in providing a length of iron tube lined with fibre, with a stuffing box and gland at the top end, by means of which an indiarubber packing was screwed down upon the cable ; and similar glands were used where the cables passed through bulkheads. One disadvantage of this arrangement was that where a number of cables and wires had to be dealt with, a considerable amount of space was taken up by these pipes in order to provide room for spanners to work in tightening up the nuts. A simple, compact, and effective method is as follows: Two pieces of wrought-iron plate are drilled with holes slightly larger than the size of the cables that are to go through the bulkhead ; similar blocks of india-rubber about ½in. thick have holes formed in them just the neat size of the cable ; the bulkheadis drilled with clearing holes ; a slab of rubber and an iron plate are placed on either side of the bulkhead, the cables are drawn through, and then the plates screwed up tight. By this means pressure is put upon the rubber, which tends to make the holes through which the cables pass smaller, so that the cables are gripped and the holes are left watertight. The arrangement was used by the author throughout the Japanese battleship "Fuji," both for decks and bulkheads. Fig. 11 shows a grouping of cables through such glands at the watertight bulkhead alongside the entrance of an ammunition passage. Many ships fitted at Portsmouth have

Digitized by Google

rubber-packed plate glands, though these are fitted only on one side of the bulkhead.

A new arrangement (Fig. 11A) was introduced by the British Admiralty in 1898. Brass glands of tubular form screwed to take a nut at one end, and having central holes, previously tinned, about ¼in. larger in diameter than the cable intended to pass through, are inserted in the bulkheads and made watertight on

FIG. 12.—Diagram of Admiralty Distributing System.

the iron by means of red lead. The lead-covered cable is drawn through, and its tape stripped back to bare the lead at the gland ; a split tinned ferrule is then inserted to fill the clearance space around the cable, and the whole is then sweated up solid by means of a blow-pipe. This is a rather tedious method until the men get accustomed to it, and there is some danger of overheating the insulation unless care is used : once the cables are tightly drawn through and sweated up, they have a neat and solid appearance; but they cannot be drawn back, and when repairs become necessary it seems likely that the cables will have to be cut, which is a great disadvantage.

Distribution System.—The main circuit cables from the switchboard pass, in the case of the heaviest circuits, through junction boxes, into which they split usually into two branches protected by fuses. Each of these branches then passes through a series of section boxes, which are circular watertight boxes containing a switch and four pairs of terminals for the attachment of fuses

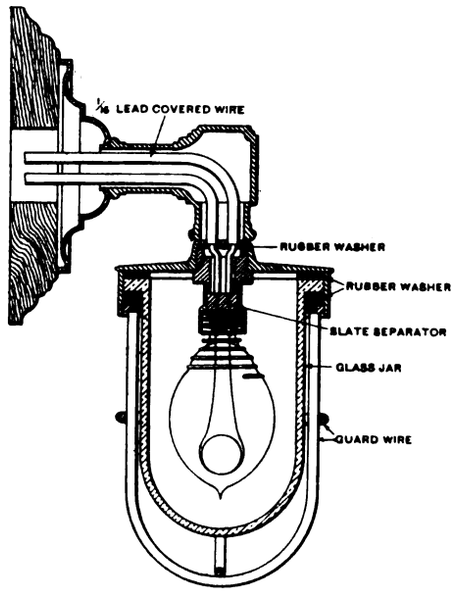

FIG. 13.—Admiralty Pattern Watertight Bracket.

and the branching of cables. Each of the four pairs of cables running from a section box terminates in a distributing box, which is a similar box to the section box and contains fuses and a double-pole switch. From each distributing box eight pairs of wires are taken, each pair leading direct to the terminals of one lamp. Fig. 12 illustrates the arrangement. As explained in the next section no lampholders, properly speaking, are employed. This distributing-box system was introduced into British warships about 1892. It is a modification of a method previously developed and used in wiring hotels, blocks of mansions, and such like places. Its advantages are that it enables the electric light system to be entirely laid out without any joints or branches in wires, thus dispensing at once with what is usually an important source of trouble. In the event of any part of the system becoming injured, it can at once be switched off at the nearest distributing or section box, and the working of the system in general is not interfered with. The system allows of the work being rendered more completely watertight than could otherwise be accomplished. The lead covering of the wires is stripped back sufficiently to enable the wires to enter the terminals in the box ; the lead is then

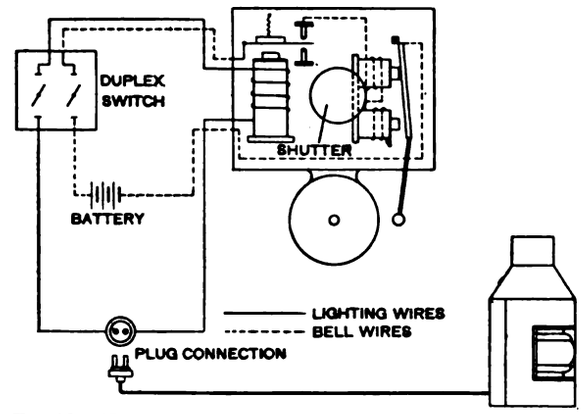

FIG. 14.—Navigation Lights Alarm, "Fuji" and "Shikishima."

sweated to gland plates, which are made watertight with red-lead packing. While there are no single-light fuses employed except in distributing boxes, it is usual to employ single-light switches placed close to the fittings for all lights except those in crew spaces and magazines, which are controlled in groups.

Double-wire lighting circuits are universal. H.M.S. "Polyphemus" was the only British ship in which single wiring was employed, and this was soon converted. Concentric systems, with or without

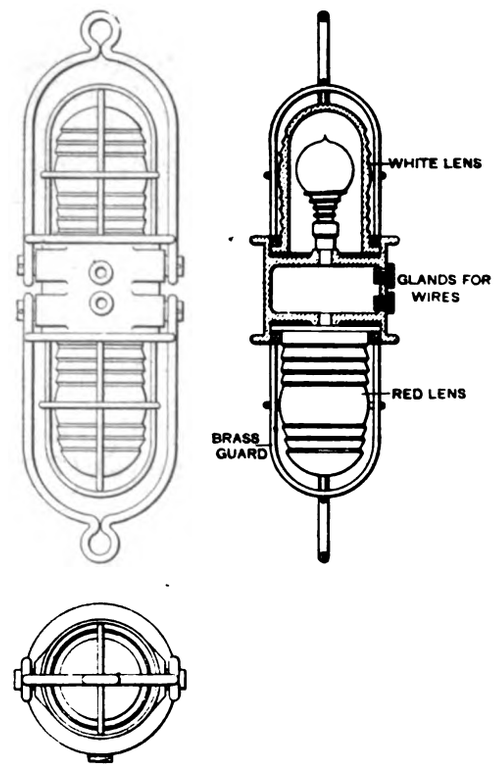

FIG. 15.—Ardois Lantern.

the outer conductor earthed, have been frequently advocated for warships, but they do not lend themselves so readily to the repair of small injuries as the twin-wire circuits employed.

Fittings.— Fig. 13 illustrates a typical Admiralty watertight fitting, showing the method of wiring. The lead-covered wires are drawn through an indiarubber washer pierced with two holes, which fits tightly into the neck of the fitting, thus excluding moisture ; the lead and the insulation are then stripped back, and the bare wires led through holes in a slate disc which forms a separator ; no lampholder, properly speaking, is used, but the ends of the wires are turned back with pliers to form hooks, and on to these bottom loop

Digitized by Google

lamps, having twisted spiral platinum loops, are hung. Loop lamps are used because they best stand vibration and shock due to gun fire. But this method of wiring is capable of considerable improvement. If the hooks in the wires are not properly formed and are not of exactly the right length, bad contact and sparking result and the wires are burnt. If from any reason the hooks get injured or broken off, little pieces of wire have to be soldered on, which is not good. It would be much more satisfactory if the wires terminated in fixed contact blocks, and the fitting, wired complete and provided with spring contact plungers, were then independently attached. In the "Shikishima," combination fittings, carrying electric lamps and candles, were wired in this way by the author with success, the removal of four fixing screws allowing the fitting to be bodily taken away without disturbing the main wiring.

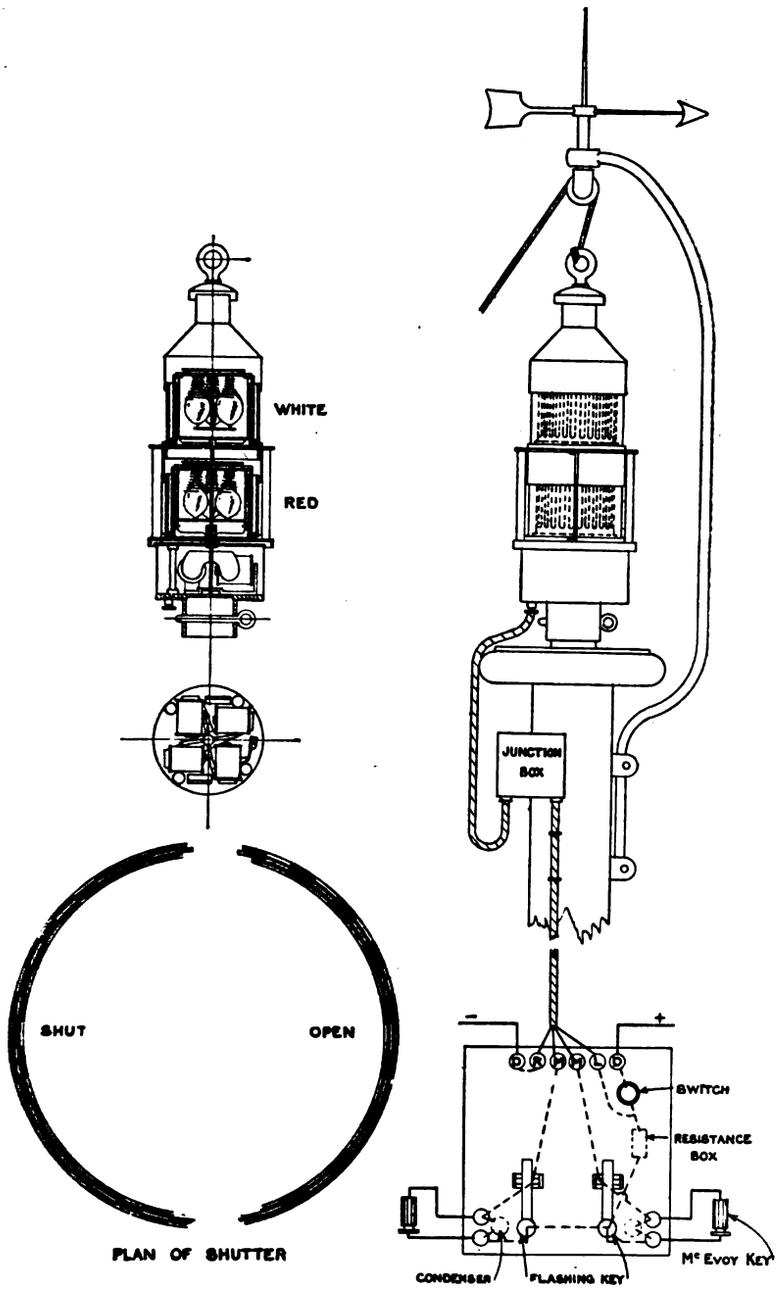

FIG. 16.—Double Mast-head Flashing Lantern, "Scott" System.

Signal Lights.—Every ship of course carries the ordinary international navigation lights, port side red, starboard side green, and mast-head white, which must be alight all the while the vessel is under weigh, together with white riding lights, which have to burn when the ship is at anchor. In British ships, so-called "position lanterns," two in number, are carried on the ensign staff when at anchor. In order to provide against failure of the navigating lights, the lanterns sometimes contain two lamps with an automatic switch for throwing the second into circuit if the first fails. This does not, however, make a good arrangement, because both lamps cannot be placed in the focus on the Fresnel lens, and if one is right the other one must be out of position. Tell-tale alarms (of which there are several kinds) are used on some ships to give warning if one of the navigating lights fails. Fig. 14 shows the arrangement devised by the author for the "Fuji" and "Shikishima." An electric bell is provided with a relay wound to one-tenth of an ohm and carrying the full current of the 50 c.p. lamp employed, say 2½ amperes. This relay magnet holds a spring contact out of connection with the bell circuit while the lamp current is on. On the failure of the lamp current, the spring contact completes the bell circuit, and the bell rings continuously. A duplex switch in one watertight case switches both lamp and bell circuit on together. A plug connection is attached near the lamp position, so that the lamp can be removed without disturbing the wiring. The bell circuit can be tested by merely switching on with this plug connection out, when of course the bell will ring if all is in order.

The Ardois lantern is largely used abroad for speed signalling. This lantern (shown in Fig. 15) is really a double lantern, one half having a white Fresnel lens and the other a ruby lens, each enclosing a 50 c.p. lamp. As used by the Japanese, the lantern is hung over a sheave from the fore starboard yard-arm, this sheave being surmounted by a single lantern of similar design showing a white light. When the white light in the movable lantern is shown burning close up to the fixed light it means "Full speed ahead," while the red light in this position indicates "Full speed astern." If the white light is shown half-way between yard-arm and rail it means "Half speed ahead," a red light in the same position indicating "Half speed astern." When the movable light is shown quite low down, it means "Slow speed ahead," and the red light in the same position "Slow speed astern" The white lenses are slightly obscured, because it is thus more easy to see the two separate lights when close together than if clear glasses are used. Two white lights and a central red one, in lanterns on the after-bridge rail, are used for the same purpose, and screened so that the light shows only astern. Among minor signals may be mentioned that employed to indicate "Admiral aboard." On British ships, three lamps are hung respectively at the ends and centre of the after-bridge rail, and one from the military top; on Japanese vessels three lamps are hung in triangular fashion from the after military top. The same three lanterns hung in various positions are used by the Japanese for other signals.

For general fleet signalling, flashing lamps carried at the truck of the foremast are in fairly general use. They are designed so that any communication can be effected by the use of the ordinary Morse code. In one design of mast-head lantern due to Capt. Scott, and made by Messrs. Armstrongs, the lamps, which burn continuously, are enclosed in a lantern surrounded by two louvre screens, one fixed and the other movable. The movable screen is attached to the armature of an electro-magnet, through which currents are sent when the signalling key is depressed. The lantern may be arranged so that openings in the louvres coincide and the lights are visible when everything is at rest, the movement of the screen cutting off the light and thus representing the interval between the signals, or *vice versa*. A modification of the Scott lantern as used by the Japanese is shown in Fig. 16 It consists essentially of two lanterns, one above the other, the lower one being enclosed in a ruby glass screen. There are independent signalling keys for the two lanterns, the contacts of which are shunted by a condenser and resistance to kill the sparking. In the figure the screen is shown to a larger scale for clearness. The British mast-head lantern is of different design, the lamp current itself being interrupted by the signalling key. The United States Navy uses for fleet signalling four Ardois lanterns, the upper light in each being red and the lower white. These are suspended about 10ft. or 12ft. apart on a couple of wire jackstays from the after-mast. A special controlling switch is used, having sets of contacts corresponding one to each possible combination of four lights, the two lights in one lantern never being used together. Each combination denotes a letter of the alphabet or a figure. By moving the switch-handle about the top dial of the switch and depressing at the proper contacts, words are spelt out.

Searchlights.—The searchlight installation is usually considered one of the most important sections of the ship's equipment, and use was found for searchlights five years before electricity was used for the general illumination of ships. The first projector was installed in 1876 in H.M.S. "Minotaur." It had a vertical lamp burning square carbons, a parabolic mirror, dioptric and diverging lenses, and flashing screen. The lamp was hand-fed and took alternating currents. In 1878 the Siemens holophote projector, with automatic lamp, was tried on H.M.S. "Triumph"; and many other forms of projectors and lamps were experimented with between that date and 1881, when the "Inflexible" was fitted with a Mangin projector, having a Mangin mirror instead of dioptric lens, and an inclined hand-feed lamp, current being furnished by a Gramme dynamo. The Mangin mirror is ground to spherical surfaces, the front and back having different radii of curvature. The parallelism of the beam is due to refraction through the thick glass between the front surface and the silver surface of the back. This remained standard in our navy until about 1893, when it gave place to the Parsons mirror, which is a thin parabolic mirror of high quality. The Mangin system is, however, in use by most foreign navies. The inclined hand-feed lamp is still the standard of the British navy;

Digitized by Google

the carbons are tilted about 20deg. from the vertical, and the light falling upon the mirror has its maximum intensity at or near the centre of the mirror. On the Continent and in the United States automatic horizontal carbon lamps are coming into favour. The crater of the positive carbon is, of course, turned towards the mirror, the arrangement in this case giving the maximum intensity of the light at the outer edges of the cylindrical beam. The British War Office has also adopted the horizontal carbon lamp for its standard projectors. The ascending current of air is apt to displace the arc, which is specially inconvenient with horizontal carbon lamps. To get over this difficulty the Schuckert projector, Fig. 17, which is the standard in the Austrian Navy, is fitted with a soft iron ring surrounding the carbon. This ring becoming magnetised when the current flows produces a magnetic field along its axis in which the carbon lies, and so keeps the arc in the proper position.

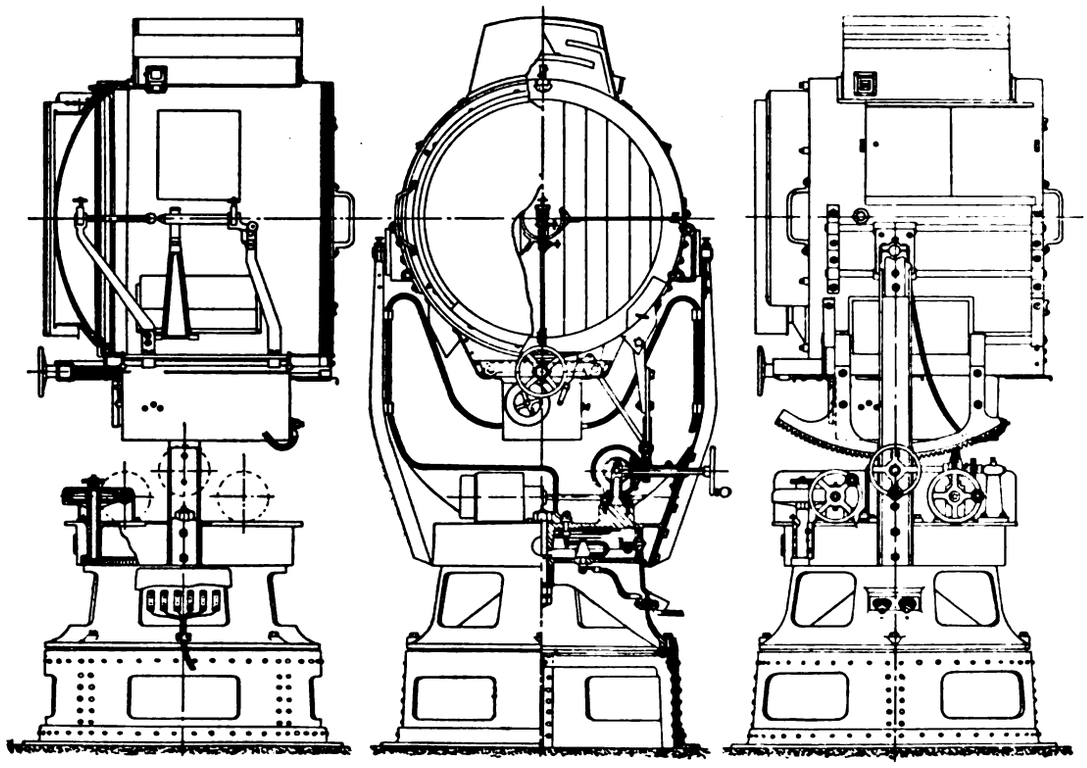

FIG. 17.—Schuckert Automatic Projector.

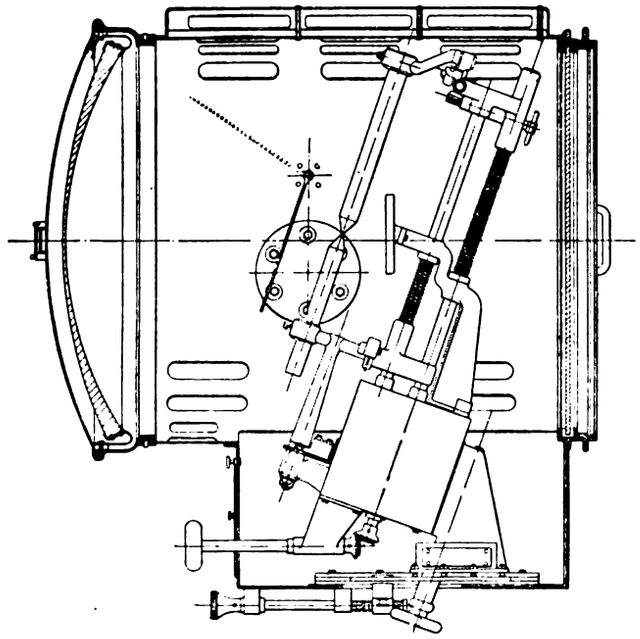

FIG. 18c.—Siemens Automatic Projector.

It is now becoming common practice by foreign nations to operate searchlights from a distance. An observing officer can see the object illuminated very much better if he occupies some different position from that of the searchlight, so that he does not have to look along the beam. But as he must have a means of directing the light, it is becoming common to provide projectors with electric motors, one to train and one to elevate the projector barrel, including lamp and mirror, and also to fit projectors with automatic lamps. This operation is specially advantageous as regards projectors fitted at the tops of the military masts which can be conveniently operated from the bridges. Fig. 18 shows a Siemens electrically controlled projector of this kind. It is worked by a combination switch consisting of two motor starting switches mounted at right angles to one another and worked by a single handle. The operation of directing the searchlight is done by moving the switch-handle precisely as if one had hold of the back of the projector itself. The projector is instantly stopped upon a given object by bringing the handle to the "off" position, which short-circuits the motors. As fitted on the bridges of ships, projectors have two positions, a working position right out, and a stowing position in board. At the stowing position they are secured by chains and turn-buckles to anchor-plates in the deck; in the working position they are secured by a small eccentric motion, worked by a hand-lever, which lifts the projector base slightly from its trolley wheels and jambs it on to the underside of a flange in the rail on which the projector runs. Searchlights are used a good deal now for long-distance signalling, and very great distances indeed have been covered. The common way is to make use of a round disc suspended on a spindle running through the projector barrel between the lamp and the mirror, and vibrating this disc by means of a small lever-handle on the spindle. The arrangement is seen in Fig. 18. In some recent foreign projectors a flashing screen, resembling somewhat a Venetian blind with the laths vertical, has been fitted in front of the front glass; the laths are linked together, and their movement from the

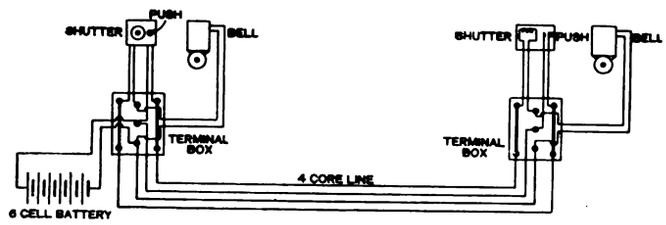

FIG. 19.—Voice-Pipe Bell Instruments. Diagram of Connections.

Digitized by Google

position in which the full light is shown to that in which all the light is cut off, is controlled by a small lever-handle mounted at the side.

Voice-Pipe and Bell Communication.—The problem of maintaining communication between the several compartments, cabins, and military positions in a warship is not less important than the problem of maintaining general illumination, but it is far less successfully solved. As regards the communications between officers in their cabins and their subordinates and sentries, a simple system of bell signals with annunciators or "shutters" is all that is required; but communications between the navigating officers on the bridge and the engine rooms, and between combatant officers in the conning tower and the gun and torpedo stations, for

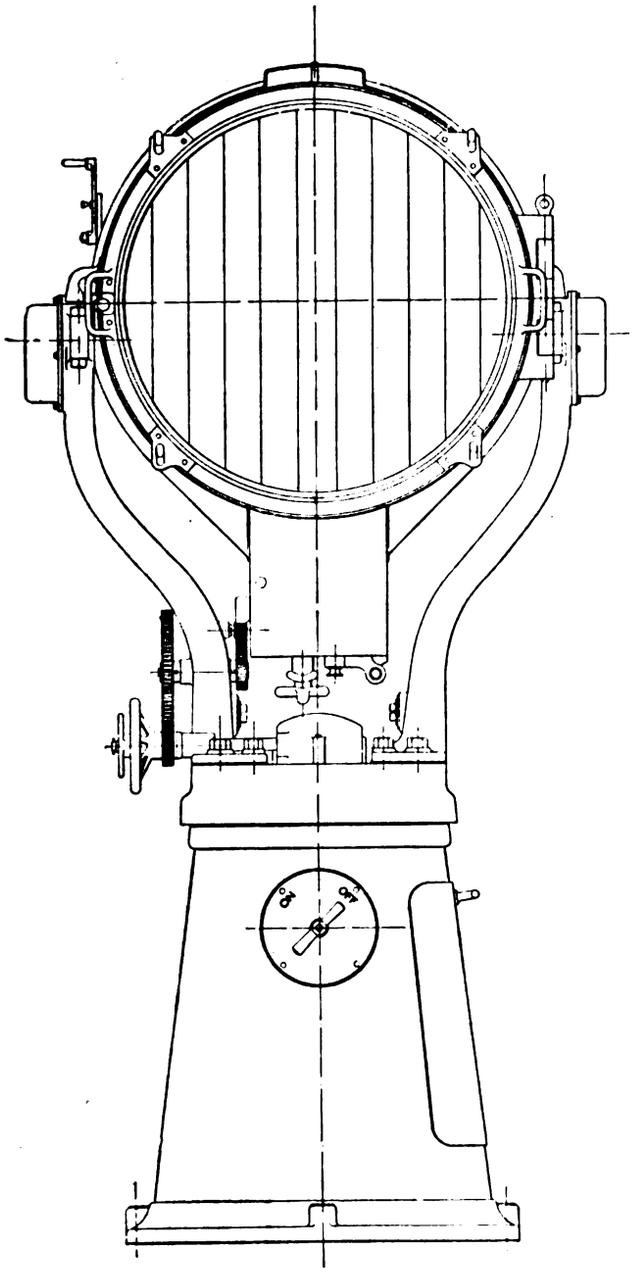

FIG. 18A.—Siemens Automatic Projector.

example, may often be of a much more complex and special character than can be easily given by a simple code of bell signals. Beyond a certain point, means of verbal or telegraphic communication becomes necessary. Such communications in our navy are effected by speaking through copper voice-pipes of 2in. diameter, fitted with whistles or electric bells, pushes, and shutters, the latter serving merely to direct attention to the voice-pipe. These electric-bell communications are very extensive in a modern ship, the number of points from which verbal messages can be sent or received being about 100 in the battleships of our "Majestic" class and about 140 in the "Canopus" class. A greater elaboration, however, than in any other ships afloat was affected in the Japanese battleships "Fuji" and "Yashima," which were equipped with as many as 256 electrically-connected speaking points, in addition to 44 cabin bell-push points. The connections between stations are effected by four-core cable, the conductors being 1/16, separately insulated with rubber, and covered with different-coloured cotton coverings to facilitate making and tracing connections. The electrical connections of a pair of instruments are given in Fig. 19. When, as is usual, several pipes and instruments occur at the same station, all the branching and jointing is done in terminal boxes. One bell is usually fitted common to the group, and one six-cell battery supplies several groups, the connections being made through suitable battery terminal boxes. The whole system is watertight, and no jointing of wires is done outside boxes.

The problem of communication is, however, not solved by the present arrangements, the difficulty being that when the electric bells have done their duty, and the officers who wish to communicate are at the opposite ends of the voice-tube, there is often so much extraneous noise that it is impossible for them to hear one another. It has been usual in recent years carefully to insulate the tubes from

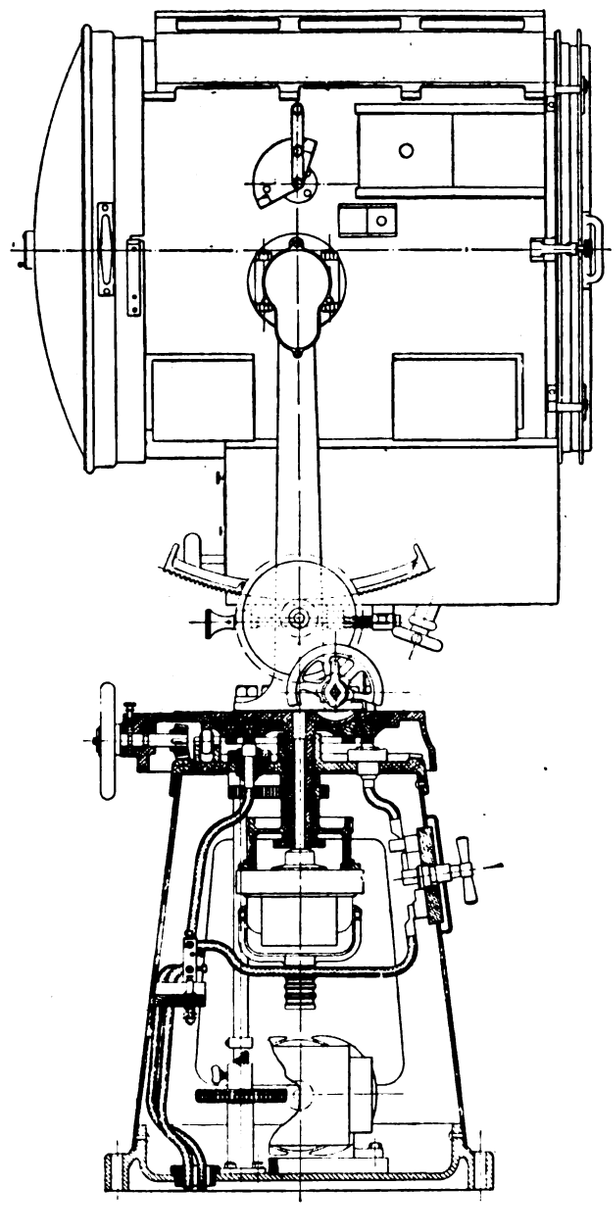

FIG. 18B.—Siemens Automatic Projector.

the main structure of the ship, so that they shall not pick up sounds by conduction, and the device has been employed of leading the speaking-tubes to about six exchange stations where messages are received and transmitted, so that the length of tube spoken through between point and point is reduced to the smallest limits. The transmission of messages at exchange stations, however, introduces delay and sometimes error.

Telephones.—The failure of voice-tubes has given telephones their opportunity, the speaking qualities of the latter being practically independent of distance. Among the earliest to use telephones on warships were Russia and America. One of the best forms of naval telephone, and one that is now being largely used, not merely by the British, but by many other navies, is Alfred Graham's. It is a loud-speaking instrument, the transmitter taking the current of four or six large agglomerate Leclanché cells, and operating without an induc-

Digitized by Google

tion coil. The transmitter is of granular type, enclosed in a water-tight case. It is turned half-round every time the telephone is used by the switch which puts the line connections from "ringing" to "speaking." In spite of the large power employed there is no hissing. The receiver is contained in the same case. A considerable number of British battleships and cruisers are fitted with voice-tubes and bells between the port-engine room and the bridges and conning towers, and with these telephones between the starboard-engine room and the bridges and conning towers, the intention apparently being to gain extensive experience of the relative efficiency of voice-tubes and telephones under identical conditions. Telephone connections in a typical case are shown in Fig. 20. The most advanced instance of naval telephones yet fitted is to be found in Her Majesty's new yacht "Victoria and Albert," which has a large telephone installation. Trials are also being made of the applicability of these telephones to communications between casements.

It would appear, however, that during actual warfare, amid the noise and rattle of quick-firing guns, any instrument that depends upon the transmission of the human voice must fail. It is reported that in the battle of Santiago the Americans found their telephones useless. Unless a large number of men are to be told off as messengers to carry orders, what seems to be wanted is a system of printing telegraphs, the instruments being of a not too sensitive character, so that they could work without giving false signals due to vibration and shock, the general design of the instrument being somewhat

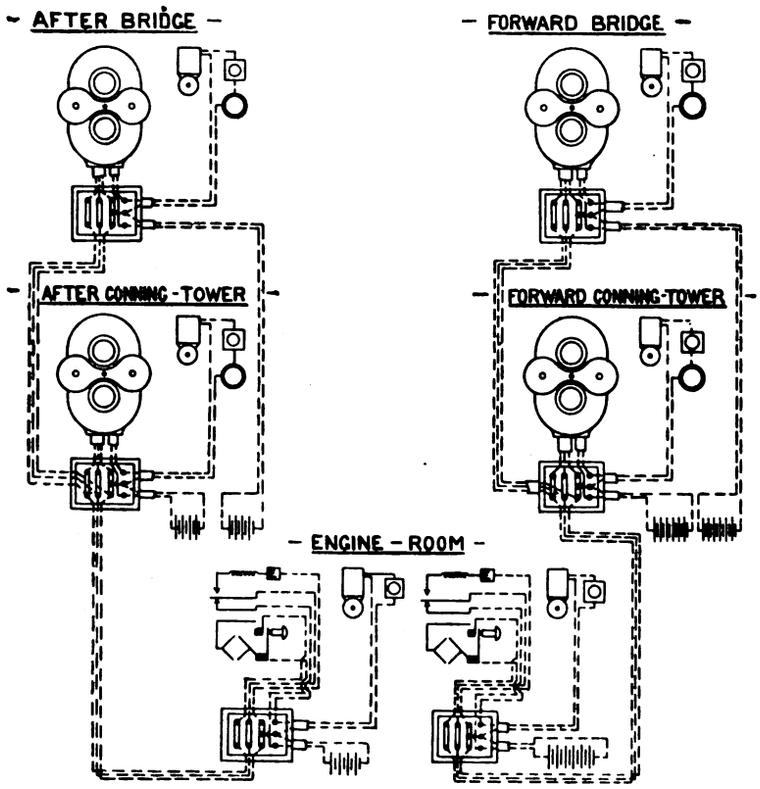

FIG. 20.—Graham's Loud-Speaking Telephone Connections.

after the fashion of that used by the Exchange Telegraph Co, printing in ordinary Roman letters. Such an instrument would have a relatively slow speed of action, but its result would be more positive, inasmuch as the message could be read by a person without a telegraphic training, and if by chance a false letter were printed, it would not necessarily prevent the word from being recognised. Probably its speed—12 to 20 words a minute—is as quick, all things considered, as the average voice-pipe communication now. Of course messages making inquiries or giving instructions in accordance with understood requirements could be transmitted by abbreviated signals.

Before leaving the subject of communications it may be mentioned that steps are being taken to introduce into the navy the Sullivan galvanometer for enabling ships at sea to speak with the land through ordinary submarine cables. There is some prospect also that warships will make general use of the Marconi telegraphic apparatus for fleet and ship-to-shore communications. This apparatus proved very useful in the 1889 manœuvres, and equipments have since been supplied to some of the battleships of the Channel Squadron.

Among internal bell communications may also be mentioned alarms connected with thermometers for calling attention to the attainment of certain temperatures in magazines, coal bunkers, &c. The arrangement is obvious.

(To be continued).

ELECTRICITY WORKS ACCOUNTS.

Dover Electricity Supply Co. (Ltd.).

Another year's accounts of the interesting undertaking at Dover are before us. The results, on the whole, are most satisfactory, culminating, as the year's operations have, for the first time, in the distribution of a dividend of 3 per cent. on the ordinary shares. Nor is this ultimate result quite a fair measure of the position of the concern; for it must be observed that the average total revenue obtained per unit sold is at Dover far below the mean of company worked stations, with double the output. In fact, the mean total revenue per unit at Dover is below the average of municipal stations with higher outputs.

Last year the increase in the connections to the mains raised the total by 10 per cent., with 85 new consumers. The total output sold showed an advance of nearly 24 per cent. The traction load demanded a maximum supply of 175 kw., while the consumption on this account reached 244,287 units, or no less than 46·6 per cent. of the total output. The public lighting absorbed another 16 per cent. of the total output. Unfortunately the official accounts do not give the total maximum supply demanded, but only the separate figures of the supply demand for traction and for lighting. From these figures we find the traction load factor to be about 15·9 per cent. and the lighting one 11·7 per cent.

There has been a general reduction in the costs, and, while a few of the items are still unsatisfactory they are balanced by some excellent results in other departments.

We are surprised to find the fuel item still keeping so high—quite 0·3d. above what, in our estimation, it should be. The other generating charges, including the item of repairs and maintenance, although this has increased, are all satisfactory.

Thanks to the influence of the very moderate management and property charges, the aggregate costs are decidedly below the average, notwithstanding the somewhat high works costs.

In the following table are repeated particulars relating to this concern, during the four complete years it has been in operation:—

Year	Equiv. lamp connection.	Units sold. Total.	Sold for traction	Sold for public lighting	Total rev. per unit.	Total cost per unit.	Working profit. Total.	Working profit. % to mean capital	Ord. div.
1896	7,904	154,200	...	87,984	4·42d.	5·13d.	-£456	-0·92	nil
1897	10,137	234,074	27,116	78,624	5·38d.	4·17d.	1,778	3·13	nil
1898	20,000	423,057	179,844	83,459	4·3·d.	2·92d.	2,533	3·80	nil
1899	22,000	523,829	244,287	84,192	4·07d.	2·59d.	3,239	4·43	3%

The Folkestone Electricity Supply Co. (Ltd.).

Our second table refers to a very near neighbour of Dover—viz., Folkestone. The accounts which are summarised cover the period of a year and a fraction between the date of commencement of working and December 31 last.

A very superficial study of our analysis is necessary to show how rapidly this undertaking has reached a satisfactory position. In the first complete year of working the cost sheet presents a most gratifying aspect considering the low output (303,116 units sold) and load factor (6·5 per cent.) upon which the results were obtained. Among the items of works costs and management charges, there is not a single one which to us does not appear to stand well below the average under similar conditions.

In view of the very moderate average revenue received per unit the working profit of £2,084, representing 3·99 per cent. of the mean capital expended, is a most creditable performance. We should like to have seen something more substantial put by to reserve before the distribution of a dividend like 4 per cent. As it is, nothing having been paid in 1898, the call made upon last year's gross profit was only about £42, since £405 was brought forward from the preceding year, and more than covered the £400 placed to reserve. The dividend absorbed £1,900, leaving about £142 balance carried forward;

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,
1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.
Telephone: 949 Holborn. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to THE EDITOR.

All letters for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited. The well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. ELTON YOUNG, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. FISHER and J. C. H. DARBY. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. PHILLIPS. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. FISHER. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C RAPHAEL. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof J. A. EWING, M.A. New edition ready in March, 1900. Price 10s. 6d., post free

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 3d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 2s. 6d., post free. Ready March 3, 1900.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. AYRTON. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DANE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICE.

Last week's number of "THE ELECTRICIAN" completed Vol. XLIV. With this week's number is issued (Gratis) the Index to the Volume.

Complaints of non-receipt should be promptly made to the Publisher.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (950 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

THE "JAMES FORREST" LECTURE FOR 1900.

SIR WILLIAM PREECE delivered, on Monday evening last, the eighth of the series of "James Forrest" lectures before the Institution of Civil Engineers. He took for his subject "The Relations between Electricity and Engineering." The discourse, which was illustrated by numerous experiments and lantern slides, occupied somewhat longer than the allotted hour; but even this interval was all too short for the adequate consideration of so ramified an engineering topic. The prodigious task of recounting the relations of electrical science and practice to engineering is not one that can properly be performed in a single lecture of only an hour's duration. Doubtless the lecturer felt this as keenly as the most sympathetic of his hearers, for he abandoned from the outset all attempts to discuss the subject on the philosophical basis of broad principles, and confined his discourse almost exclusively within the limits of a category of the miscellaneous uses to which electricity has been, and in future may be, put to achieve engineering results. We confess to feeling disappointment at his choice, but the treatment he adopted was one that probably was best suited to his favourite style, and it certainly lent itself more readily to a popular review of the subject. Nevertheless, we hope that at some future date a "James Forrest" lecture will be given in which there shall be discussed on logical, rather than historical, lines the interconnection between electrical means and engineering achievements. Not that the fundamental phenomena of electricity were passed unnoticed by the lecturer. On the contrary, to many electrical engineers present, accustomed as they are to hear recondite matters of electrical practice discussed between the same four walls, the preliminary display of experiments may have appeared childishly simple. These, however, should reflect that the audience was composed mainly of civil engineers—men who, perhaps, had spent all their long lives in building docks and canals, and who hitherto had missed every opportunity of seeing a magnetised poker pick up iron nails. But it certainly was irresistibly comical to see a select group of some six or seven of these venerable gentlemen crowd in front of the lecture table round a bit of platinum wire, striving to discern its ineffectual radiance, while over their heads the electrolier

Digitized by Google

shone brilliantly by the selfsame world-familiar process. What need of ruddy-glowing platinum wire amid such a profusion of carbon filament?

Our abstract of the lecture, printed on another page, will enable readers who were not present to learn its contents and scope. We need not summarise all those contents here, but different sections of our readers will be interested in various ways by the following statements, among others, made during the discourse. *Apropos* of alternating currents, the lecturer observed that "MAXWELL proved the identity of electricity and light by showing that they moved through the ether with the same velocity." The same physicist, he said, had pronounced the discovery of the reversibility of the dynamo to be "the greatest invention of the century." Of the extensiveness and ease of applied electricity, no man holds higher opinions than Sir WILLIAM PREECE: "No magician or poet," he said, "ever conceived so potent a power within the easy reach of man." Under the somewhat startling heading, "The Annihilation of Space," the lecturer referred to several applications of electricity familiar even to budding civil engineers: "Sitting on the shores of the Atlantic in Ireland, one can manipulate a magnetic field in Newfoundland so as to record simultaneously on paper in conventional characters slowly written words. Thus we have bridged the ocean and annihilated space. We do this on a smaller scale in our own domestic circles." While thus dealing with telegraphic matters, the lecturer made the announcement that "the Post Office is using aluminium for telephone circuits," and that he had "recommended its use on a very large scale in the interior of Africa." Incidentally, he stated his belief that the "Cape to Cairo" telegraph line would be ten times better if of aluminium than of iron. We must not omit reference to a novel theory of electrolysis which, we feel sure, will interest our electro-chemical readers. Referring to the action of an electric current upon various conductors, the lecturer said that "in liquid conductors the motion probably becomes revolution. The result is decomposition by the activity of the centrifugal force overcoming chemical affinity. The atoms fly away in fixed determined lines and collect at opposite poles." With regard to wireless telegraphy, Sir WILLIAM stated that there was "no commercial business in it," and that the Post Office had been developing it for 16 years and several extensions were now in hand. Mr. C. E. GROVE recently read a voluminous and comprehensive Paper on "The Electrical Equipment of Ships of War," before the Institution of Electrical Engineers. This Paper is now appearing serially in our columns. Sir WILLIAM PREECE compressed the whole of this subject into the following short paragraph:—

> The battleship is the home of electricity. It controls the rudder, it ventilates the interior and the living space of the ship, it forces the draught and assists the raising of steam, it revolves the turrets, it trains and controls the fans, it handles the ammunition, it purifies the drinking water, it lights up the ship internally, it enables the captain to sweep the horizon with the brilliant rays of the search light, and to communicate with his tender or with his commanding officer across space independent of weather, night, season, fog or rain.

Our readers will find it of no little interest to compare these statements with what Mr. GROVE has said on the same subject.

These few quotations will serve to indicate not only the extensive scope, but also the novel treatment adopted by the lecturer. We observed a fair sprinkling of electrical engineers in the audience. These, notwithstanding the elementary nature of the early part of the discourse, must all have felt when the lecture was ended that they had heard many things they had never heard before, and had had presented to them in an altogether novel light many of the familiar everyday facts of electrical engineering.

ELECTRICAL CONDUCTORS AND DIRT.

BY A. A. CAMPBELL SWINTON.

Everyone must have noticed how electrical wires and fittings gather dust. Hot-water pipes have a similar tendency, and for a long time I was of the opinion that the action was similar in both cases, and was due to air currents produced by heat. Recently, however, I have had reason to alter my views, and the matter appears to be of sufficient interest for detailed description.

In a new office I have now occupied for five months there are in my own room five plain pendant fittings. As the ceiling is of concrete, and as it was necessary not to disturb the tenant above, these pendants all consist of plain flexible cords of the usual twisted pattern, which start from ceiling roses on the wall near the cornice, and are led through insulated eyes across the ceiling to the points from which they hang. The supply is the continuous-current supply of the Westminster Co. at 200 volts. Three of the pendants are upon one switch, the two others being upon another switch. Of the set of three, two are of 16 c.p. and one of 32 c.p. I mention this latter fact, though it has nothing to do with the phenomenon observed. All the lights are in practice used at once, so that in this respect the conditions are the same in each case. The following, however, are the results, which are sufficiently remarkable to deserve notice.

Within a week or two of my entering into occupation of the office and using the lights it was observed that, whereas the three flexible cords connected with one switch remained clean, the two cords on the other switch were rapidly accumulating dust. The latter were repeatedly dusted, but the effect always repeated itself. At present, after some five months use, while the one set of three cords are still comparatively clean, never having been dusted, the other set of two cords are thickly covered with an aggregate of dust particles, which in some places project fully one quarter of an inch from the cord. Further, while the plaster of the ceiling in the case of the set of three cords is absolutely white, and the ceiling roses at the ends of these cords retain their original colour, the ceiling immediately above the set of two cords is blackened with a well-defined broad dark line, while the ceiling roses that serve these two cords are also covered all over with a dark deposit.

Now for the reason of this strange phenomenon. It is very simple. In the case of the set of three pendants the flexible cords and ceiling roses of which do not become dirty, the switch is in the positive pole. In the case of the other set of pendants, whose cords and roses become covered with dust, and which even blacken the ceiling with which they are not in contact, the switch is in the negative pole. Now, as is well known, the negative conductor in the street mains has a tendency to earth itself to an extent which is sufficient to cause the negative lead to be always almost at the same potential as earth. Consequently, the positive conductor is always at nearly 200 volts potential above that of earth, and therefore above that of the dust particles present in the atmosphere. This point has been tested in my office with a voltmeter, with the results that from the negative there are only about 30 volts to earth, while from the positive there are 170 volts to earth. The reason for the effects observed is thus obvious. In the case of the three pendants, whose switch is in the positive, it is only when the switch is turned on a few hours per diem out of the 24 that there is any appreciable difference of potential between the cord and the surroundings. Even then it is only one conductor in the cord that has this potential, and the exterior of the covering very possibly always retains zero potential. In the case of the other set of two lamps, whose switch is in the negative, the result is far different. When the switch of this set is turned on, no doubt the conditions are similar to the other set when the latter's switch is also turned on. But during the many hours every day when the switch is turned off, in the case of the two-light set, both of the conductors remain constantly at a potential 170 volts above that of its vicinity. The dust is therefore caused to deposit upon the cord and upon the ceiling rose by electrostatic attraction. No doubt the use of 200 volts, which will

Digitized by Google

give four times the attraction afforded by 100 volts, has made the effect more marked in this particular case.

I should not have thought it worth while bringing the above facts forward publicly had they not been so marked as to be a serious nuisance in the case of the pendants whose switch is in the negative. From the point of view of the wiring of decorated rooms in a town with an atmosphere like London, the matter is of very considerable importance. It will be found that with the switches in the negative, an amount of dirt will be deposited in a few weeks that would take years to accumulate with the switch in the positive. I am well aware that from a totally different point of view, in damp situations, there is an advantage in putting the switch in the negative, for the reason that otherwise the metallic mechanism of the switch is liable to be corroded away by electrolytic action. In dry places, however, where it is desired to keep electrical wires and fittings clean, I have no doubt that in an atmosphere such as we have in this great city, switches should always be placed in the positive conductor, so that the exteriors of such fittings and wires should remain as far as possible at earth potential.

AUTOMOBILE BATTERIES.

In view of the increasing attention which is being paid to the employment of accumulators for electric traction, or, as Herr Vollmer prefers to call it, "accumobilimus," he has devoted an article in No. 7 of the *Centralblatt für Accumulatoren und Elementenkunde* to discussing the relative merits of the Planté and the plug plates for particular classes of work. The Planté type possesses the great advantage that it can be discharged at a very high rate when necessary without any loss of economy, and it can also be charged very rapidly, so that a battery of 80 ampere-hours can be charged in 15 minutes. It has also a somewhat greater durability, but these advantages are counterbalanced by the great weight of the cell, its large volume, and its small capacity. Taking the lightest type of these cells, weighing 18 kilogrammes each, then the total weight of the 44 cells required to propel a vehicle to carry four persons would be 572 kilogrammes, and its capacity of 80 ampere hours at a three hours discharge rate would be about 6·15 ampere hours per 1 kilogramme of total cell weight, and about 12·8 ampere hours would be yielded per 1 cubic dcm. of the space occupied by the battery, while the distance which could be travelled by such a carriage without recharging the battery would be about 25 to 30 kilometres under the most favourable conditions.

The properties of the plug accumulator are almost the exact reverse. With smaller volume and weight it possesses a very much greater capacity, but its discharge rate is very low, and if this is exceeded at all, the capacity and durability of the cell are quickly injured. The time required for charge is very long; for instance, it would take a battery of 80 ampere-hours' capacity fully 4 to 5 hours to charge it. This disadvantage is got over by calculating the amount of current required at the normal five-hour discharge rate of the battery for the normal rate of speed of the vehicle, and determining the size of the battery from this. Assuming as before, a capacity of 80 ampere-hours at a three-hours' discharge rate, we find that the battery would have the following proportions:—

Total of 44 cells at 10 kilogrammes each	440 kilogrammes.
Capacity per 8 kilogrammes cell weight.....	8 ampere-hours.
Capacity per cubic decimetre cell volume	21·4 ampere-hours.

Provided with such a battery a four-seated carriage would travel 40 to 45 kilometres for each charge, because the vehicle would be lighter on account of the smaller weight of the battery.

From a comparison of these data, the superiority of the plug accumulator over the Planté is at once apparent, but when the life of the accumulators is taken into account, then the Planté are the most economic, as they will yield about 200 discharges, while the most that can be obtained from the plug accumulators are 150. With regard to the size of the batteries it may be mentioned that the best results which have been as yet obtained from automobiles show that they require 80 to 85 watts per ton-kilometre-hour on good level roads. When the working conditions are known, the type of accumulator to be employed can be easily determined from the foregoing considerations, the Planté cells having the advantage when the demand for current is high but the distance to be travelled is not great, while the pasted plates are most suitable for light running vehicles used for pleasure where economy is not an important consideration.

THE RELATIONS BETWEEN ELECTRICITY AND ENGINEERING.*

BY SIR WILLIAM H. PREECE, K.C.B., F.R.S.

The nineteenth century is distinguished in our profession chiefly by the knowledge we have obtained of the constitution of *matter* and of the qualities of the materials we utilise for the service of man, of the presence and characteristics of that medium—*the æther*—which fills all space, and of the existence indestructibility and protean character of that great natural source of force, motion, work and power which we call—*energy*. Electricity is only one of many forms of this energy. It is measurable in well-defined and accurately-determined units. It is produced and sold, utilised and wasted. It is therefore something distinctly objective. It has even been defined by Act of Parliament. There are four great principles underlying the practical applications of electricity: I. The establishment of a magnetic field. II. The establishment of an electric field. III. The disturbance or undulation of the æther. IV. The work done by the generation and maintenance of electric currents in material systems. It will smooth our journey over somewhat difficult ground if I commence by illustrating these principles with some elementary experiments.

When the current is alternating it is always either rising or falling and changing its direction. The behaviour of alternating is more complicated than that of continuous currents, but each are subject to well-known conditions and to simple mathematical treatment. Each has its own particular sphere of usefulness. Some of the energy is wasted in the form of heat in the conductor, in the dielectric, and in the iron; some in the neighbouring conducting mains, and some is conveyed away—dissipated in limitless space. Alternating currents differ in their frequency. Those generated at Niagara pass through each cycle 25 times per second. The favourite frequency in the United Kingdom is 50, but many installations in the United States reach as high as 130. These frequencies in closed circuits can, however, be increased to millions per second in open circuits. In fact, Maxwell proved the identity of electricity and light by showing that they moved through the æther with the same velocity—196,400 miles per second—and in the same undulatory fashion. If the alternations could be generated with a frequency of 50 billions of waves per second we should see electric waves as light rays. Electric waves and light waves differ only in their length. Hertz detected and measured these electric waves. Attempts have been made to utilise them, but so far not with much practical success.

If a conductor itself be free to move, and a magnetic field be projected through it while it is maintaining a current, it is forced into motion, and it becomes a rotating machine or *motor*. The electric energy of the current is transformed into its mechanical form. Its torque, or turning moment, depends upon the intensity of the magnetic field, on the length of the conductor, and on the strength of the current. This reversibility of the dynamo is of immense commercial value. Maxwell said it was the greatest invention of the century. Tram cars in our streets, trains on our railways, tools in our shops, and mills in our factories, are thus worked by electricity. Dynamos and motors are subject to laws and conditions so thoroughly well known that exactness is assured and waste reduced to a minimum. There is no more perfect machine than a dynamo. Motors are nearly as good. Electricity as a science is fascinating to everyone, but it is deeply fascinating to the engineer. No magician or poet ever conceived so potent a power within the easy reach of man.

The Doing of Work.—The maintenance of an electric current through a conductor means the expenditure of work upon that conductor, and this expenditure of internal work means molecular motion. In solid conductors the result is *heat*. If the current be gradually increased, this motion is similarly increased. The result is successively incandescence, white heat, fusion, and disruption. In liquid conductors the motion probably becomes revolution. The result is decomposition by the activity of the centrifugal force overcoming chemical affinity. The atoms fly away in fixed determined lines, and collect at opposite poles. In gases the transference of electric energy in the form of sparks means dissociation. Compound

* Abstract of the Eighth "James Forrest" Lecture, delivered before the Institution of Civil Engineers, April 23.

Digitized by Google

gases are broken up into their component elements under the same directing influences. Work is done upon the gas as in the previous instances. Joule established the law of the relations of current and heat upon a definite and accurate basis. Faraday developed the laws of electro-chemistry with equal exactitude. Prof. J. J. Thomson has determined the action of currents on gases. The principle of work that lies at the very root of the profession of the engineer enables all these operations to be measured in definite mechanical units.

The Purification of Matter.—The elements and their useful compounds are rarely, if ever, found pure. Impurities have to be sifted away. According to Prof. Borchers, the eminent electro-metallurgist, the world manufacture of calcium carbide for the production of acetylene gas is utilising a power equal to 180,000 H.P., that of the alkalies and the combinations of chlorine for bleaching 56,000 H.P., of aluminium 27,000 H.P., of copper 11,000 H.P., of carborundum 2,600 H.P., and of gold 455 H.P. Electroplating is one of the staple manufactures of Sheffield and of Birmingham. There are nearly 200 firms working at the former place, and over 100 at the latter. The decomposing bath and the arc furnace are revolutionising many industries. Phosphorous is now being produced in England in large quantities from corundum, and aluminium from bauxite is extending in use and being reduced in price. The Post Office is using aluminium for telephone circuits. I have recommended its use on a very large scale in the interior of Africa, where transport is so costly. We can get the same conductivity as with copper with half the weight, and at a less price, and we can put up a line telegraphically ten times better than of iron for less money.

The Annihilation of Space.—The elements of Volta and the battery of Galvani—zinc, copper and a solution of sulphuric acid—gave a convenient generator of electric currents which could be directed along wires to great distances, and thus, by establishing magnetic fields, could deflect needles in such a way as to form the alphabet and so transmit words and, therefore, thought. In wires of great length, while the initial speed is that of light, it takes time for the electric waves to rise and fall, so that the number of currents which can be sent per second is limited Between London and Liverpool the speed of speaking is virtually unlimited, but between Ireland and America it is restricted by the so-called *capacity* of the cable submerged in the ocean. This capacity absorbs energy and retards the rate of rise and fall of currents. While a thousand currents per second can be sent in the former case, only six per second are available in the latter. Nevertheless, sitting on the shore of the Atlantic in Ireland, one can manipulate a magnetic field in Newfoundland so as to record simultaneously on paper in conventional characters slowly written words. Thus we have bridged the ocean and annihilated space. We do this on a smaller scale in our own domestic circles when we press a button and ring a bell in our servants' quarters. The sound of a bell and the drop of an indicator is a message—"You are wanted in the drawing-room." When the button is supplemented by the telephone, as it is in so many houses now, you can speak your message, "We want coals," and thus the servant is saved two journeys, and you have gained some time.

The regulation of the ever-growing traffic on our railways and the safety of passengers is secured by similar means. The telegraph not only places the manager of the line in communication with every station upon his system but electric signals control the motion of every train. Trains are kept apart by a considerable space. Collision would be impossible were the human will infallible; but the world is made up very much of fools and temporary maniacs. We all do at times what we ought not to do. The annual return of violent deaths is an interesting document. When in England alone 138 persons choke themselves at their own tables, and 765 die by falling downstairs, we must not condemn the railway signalman, who is responsible for the death of only 58 in 1898. A railway signal-box is an electrical exhibition. Every line is protected by its own electric signal. Every distant outdoor mechanical signal is repeated back. The danger signal is locked and cannot be lowered to "line clear" until it is unlocked by the train itself or by the distant signalman. Mr. F. W. Webb is not only working the outdoor signals themselves by electrical energy, but he is moving the points and switches by the same means So far the experience gained at Crewe during a period of about twelve months, from the working of a signal cabin containing about 60 levers, has been such as to justify confidence and the extension of the system, and some ten cabins containing about 1,000 levers will be provided. The apparatus has been designed to work in with as far as possible the standard signalling apparatus of the London and North-Western Railway. The interlocking frames may be said to be the ordinary mechanical frame in miniature, occupying one-third of the space. The levers—about 6in. in length—are placed in two tiers, and are manipulated in the same way as the levers of a mechanical frame, consequently the signalman accustomed to the old type has nothing to learn in the new. The levers are mechanically locked by means of tappet locking, and they control carbon switches by which the 110-volt electric current is transmitted to the motors. The object of this electric working is primarily to reduce the manual labour of the signalman, and enable him to pay more attention to the movements outside his cabin; increased speed of working; the removal of obstructions on the ground caused by the numerous wire and rod connections necessitated by the present system; and, finally, a reduction in the number of signalmen employed.

Wireless telegraphy, or, as it is better termed, ætheric telegraphy, has made but small progress, owing to the simple fact that the demands for its services are so very few. There is no commercial business in it. The fascination of electricity and the sensation of breaking down space by apparent magical means have led to much gratuitous advertisement on the part of the Press. I wrote in 1888, "The influence which electric currents exert on neighbouring wires extends to enormous distances, and communications between trains and ships in motion, between armies inside and outside besieged cities, between islands and the mainland, has become possible without the aid of wires at all by the induction, which is exerted through space itself." The Post Office has for 16 years been developing this system. Several extensions are now in hand.

Transmission of Power.—It is not considered advisable to construct dynamos giving higher voltages than 2,500 volts, although in many cases 5,000 volts are produced; but these high voltages are easily and safely converted by transformers to any other higher pressures. Energy is also transformed in its continuous form by rotary converters, but in this case the process is usually the reverse. Direct continuous currents of 100 amperes and 3,000 volts are reduced to 500 volts by acting as motors to rotate generators, giving 600 amperes, for, say, tramway working. Again, at Tivoli, 18 miles from Rome, the energy of the falling water there is transmitted to Rome in the form of alternating currents at 6,000 volts, and is there converted by rotary transformers into direct currents at lower voltages for battery, traction, and motive purposes.

The sun is the *fons et origo* of all the available energy upon the surface of the earth. Coal and oil are extracted from its crust; oxygen is found in its atmosphere. Grasses, corn, fruits, and vegetables become food and fuel for beast and man. Waters are converted into vapour, forming clouds, rain, brooks, rivers, torrents, and falls. The atmosphere is disturbed by wind, and the waters of the ocean by tides. Energy is thus found available for useful work in many different forms. The problem before the engineer is how to utilise these waste energies of Nature so as to secure the best economical result. Falling water can, by a turbine or impulse wheel, convert the energy it possesses in virtue of its fall into the form of electricity. By the aid of transformers it can be raised to very high voltages; 40 000 volts is employed in California, 11,000 in Niagara. We use 10,000 between Deptford and Trafalgar-square. It can thus be transmitted to any reasonable distance, and there it can be utilised to do useful work. The waste forces of Nature are thus within our reach. The waterfalls of the Highlands may work the tramways of Glasgow; Niagara already works those of Baltimore.

We underrate very much the progress made in the United Kingdom in different industries, owing to the secretiveness of the British manufacturer. He will not report what he is doing in the Press, and the Press leaves him severely alone. Electricity as an economiser, by increasing the speed of output and by reducing waste, is as much at the disposal of the British as of the American manufacturer. But John Bull clings with affectionate and conservative fervour to the capital expended by his grandfather, while Uncle Sam does not hesitate to chuck obsolete plant on the scrap heap if, by doing so, he can increase his business. Progress in the States is also not so seriously checked by trades unionism as it is here. I am told that the Bricklayers' Union in England limits a man's daily work to laying 400 bricks, while in the States he does 1,200! This limiting of the output of labour is a much more serious tax on the nation than a war tax. It drives trade out of the country; it restricts the intelligence and lowers the tone of morality of our working classes. It is a disease to be grappled with.

Traction.—It is for traction purposes that electricity is making such gigantic strides. In the United States tramway working by its means has become practically universal. In the United Kingdom it is making rapid way, and in connection with electric lighting it is giving great economical results. The combination of the two systems is most effective. In St. Helens, in Lancashire, where 13,435 8 c.p. lamps are connected, and a small tramway system of nine cars simultaneously running is at work, the works costs have been brought down from 3·23d. per unit to 0·67d. per unit. The price for electric light has been reduced from 6d. to 4½d. per unit, and it will probably be lowered to 3½d. This is after only 8½ months' working. St. Helens is an object lesson to all municipalities, especially to Glasgow, where a very false start has been made. Electric railways are also growing apace. A bold attempt is being made by the metropolitan railways to work the existing line in such a way as not to interfere with the existing traffic or even with the permanent way. A new train of six coaches weighing 180 tons, having a motor car at each end weighing 54 tons, is about to run between Earl's Court and High-street, Kensington. Each motor car is mounted on bogies, and each bogie has two electric motors, so

Digitized by Google

that there are eight driving wheels, each bearing 6·75 tons. The driving wheels have diameters of 47in. The length of the train is 240ft. Each motor is rated at 200 H.P, or a total of 800 H P. for each motor car. But there is a wide margin, and we have already applied 950 H.P. in starting a load of 270 tons on the incline of 1 in 43. Electric traction has an immense advantage over steam traction in impressing a continuous and uniform torque or turning moment on the shaft, and consequently a continuous and uniform effort on the trend of the wheel. The action of the steam locomotive is intermittent and the bite not continuous. Hence such frequent slipping on greasy rails. Again, the maximum torque can at once be applied by the current, and, in combination with the constant effort, it increases the acceleration so that a train acquires its maximum speed much more quickly. We shall increase the mean speed of the metropolitan trains from 11 miles per hour to 15, and thereby increase the capacity of the line over 30 per cent. The stoppages on the underground railways are so frequent that the trains are always either accelerating or stopping. They never reach their top speed as they do on main lines. Electric traction enables them to start quicker and stop more promptly. On the Metropolitan the 180-ton train acquired 20 miles an hour in 200ft., and, when going at the same speed, it was stopped in 130ft.—half its length. Smart work on such a railway depends on the rate at which trains can be emptied and filled. The English system of compartments and side doors facilitates this. It would be still further expedited if we could have one platform for entry and one for exit, and one class only.

The Liverpool and Manchester Lightning Express Railway, promoted by a very powerful representative syndicate of these two great commercial centres to carry out the scheme of Mr. Behr, is a very bold and promising venture. The line is to be monorail, 31 miles long, direct between the two cities, without any intermediate station and with no crossing. There are to be cars every ten minutes. The speed is to be 100 miles per hour, and the time of transit 20 minutes. I know of no reason why this should not be done with safety and comfort.

The automobile car of the future has not yet seen the light. It will be electrical. Immense progress has been made in motors and in batteries. Lundell has shown how to store up the energy now wasted in descending hills, and to recover some of that absorbed by the inertia of the car. Although a battery has already been able to drive a car 100 miles with one charge, we are waiting patiently for the real automotor storage cell.

Electricity in War.—A strong contingent of electrical engineers has volunteered for service in South Africa. They are all scientifically-trained practical young engineers. Bicycles, field telegraphs, telephones, arc and glow lamps, cables, search lights, traction engines, and generating plant will be under their care.

Electricity has been extensively applied to the development and utilisation of explosives in both the civil and military divisions of our profession. Charges are safely fired under water and blasted in mining and demolition operations by small exploding dynamos, magnetic-electric machines or induction coils acting upon high tension fuses. Our Honorary Member, Sir Frederick Abel, has especially distinguished himself in this direction. His fuse, composed of phosphoride and subsulphide of copper, is universally used by our War Department. Time guns are thus fired at stated hours at different sea-ports by currents originating in Greenwich Observatory. Broadsides in battle-ships and guns in turrets are similarly discharged. Torpedoes are even directed by currents from the shore. The defence of our coasts by submarine mines and their explosion by currents when the enemy's ships are properly located by position-finders is the last development of the application of electricity to war. Electrical blastings has revolutionised the operations of tunnelling and driving galleries. It is much used in quarrying with great security to the men. The deepening of harbours and channels and the removal of obstructions such as wrecks and rocks are facilitated.

The battle-ship is the home of electricity. It controls the rudder, it ventilates the interior and the living space of the ship, it forces the draught and assists the raising of steam, it revolves the turrets, it trains and controls the fans, it handles the ammunition, it purifies the drinking water, it lights up the ship internally, it enables the captain to sweep the horizon with the brilliant rays of the search-light, and to communicate with his tender or with his commanding officer across space independent of weather, night, season, fog, or rain.

Sanitation.—No branch of our profession fulfils the true function of the engineer more efficiently than that which deals with sanitation. Pure air, pure water, pure food, pure soil, pure dwellings, and pure bodies are the panacea for health and comfort. Electricity helps us very much in attaining some of these qualities. An electric glow-lamp does not vitiate the air. It does not throw into circulation in the air any product of combustion. The question of ventilation is very much reduced in importance and rendered more simple to effect. Much less air need pass through our sitting-rooms and meeting-places. The air vitiated by our lungs can be easily withdrawn and fresh air can be forced in by fans worked by electric motors. Even the air during its entrance can be warmed, and impurities floating in it can be sifted out of it by the attraction of electrification. Heating by Dowsing's luminous electric radiators is very much on the increase; they consume 250 watts, which cost about ½d. per hour. In many post-offices sealing wax is melted and kept in a liquid state by currents. Water can be sterilized by ozone, a product of electrification, and even by the nascent oxygen, when broken up into its constituent elements by electric currents. Sea-water thus electrolysed supplies us with chlorine, and converts the water into a powerful antiseptic, disinfectant, and deodoriser. Its economy is, however, doubtful, and in consequence its adoption has been much restricted.

Industries.—The applications of electricity to other industrial processes are innumerable. I have time to mention only one. Mr. T. A. B. Carver, who was a pupil of Lord Kelvin and an officer on our staff in this Institution, has brought out a new Jacquard loom for weaving; 600 hooks are controlled electrically. The twill as well as the pattern is under complete management. It has been warmly taken up in Glasgow, and a factory has been started there. The pattern on this cloth is woven directly from a photo-print of the artist's design, mounted on a metallic sheet. The threads of the warp being picked up by electromagnetic action, owing to the figure of the pattern being cut away, and thus allowing the circuit to be completed by the metallic sheet.

THE PROTECTION OF PUBLIC BUILDINGS FROM LIGHTNING.

On Monday last Mr. Killingworth Hedges, who has recently been advising on the re-arrangement of the lightning conductors on St. Paul's Cathedral, read a Paper on the above subject before the Royal Institute of British Architects. He quoted from a Paper read before the same Institute by Col. the Hon. Arthur Parnell in 1884, in which an analysis of a number of disasters to buildings fitted with lightning rods showed that there were 828 separate instances of mechanical force, as against only 228 of heat, exercised on various substances by lightning. Mr. Hedges also repeated Dr. Lodge's statement that the problem does not end with the actual rod, owing to the large difference of potential existing between the conductor and earth, however well the two are connected. He expressed himself in agreement with Dr. Lodge as to the oscillatory nature of the discharge, and expressed the view that the side flash was the result of self-induction in the conductor. On one matter, however, Mr. Hedges' theory was somewhat remarkable. He considered that when a discharge occurred at one point between the thundercloud and earth, a corresponding discharge occurred in the reverse direction at another point of the cloud. He referred to these as the "downward" and "upward" discharges, and stated that he had frequently seen in Colorado "upward" flashes arising from the ground! In connection with available reports and statistics of lightning accidents, Mr. Hedges regretted that no official reports of this nature had been published since that of the Lightning Rod Conference in 1882.

Not the least interesting part of Mr. Hedges' Paper was a description of the lightning conductors attached to several important buildings abroad. On the Notre Dame Cathedral, in Paris, the main conductors are three in number, each of the two on the towers commencing at a massive wrought-iron terminal rod about 20ft. high and 4in. square at the base. To this a wrought solid iron rod about 1in. square is secured by straps, and run in lengths, jointed at intervals, over the roof and outside the tower to the ground. This rod is supported about 7in. from the lead roof and stonework by stanchions insulated by half-round stone or porcelain insulators secured by shackles. At a later period a copper strip had been connected to each of the conductors at the roof and run independently to the ground below. The spire has an elaborate finial with numerous points and this appears to be connected to earth in a similar manner, and also to the crest running along the ridge of the roof. The speaker considered this method of protection to be a source of danger at present. The flash received by one of the main rods had two paths open, one by the old iron conductors and a second by the new copper band. The current could be prevented from dispersing over the lead roof by the insulators of the conductors, and owing to the resistance of the joint would consequently jump from the central rod to the small copper one.

On the Cologne Cathedral he considered the protection far more advanced than that of Notre Dame. Stranded copper cables are used, run through galvanised iron stanchions with flat feet by which they are bolted to the stonework. To avoid galvanic action, the eyes of these supports are bushed with lead. They keep the conductor about 7in. away from the structure so that the cable can be stretched tight by tightening screws and not run round projections. A somewhat similar arrangement is used for the horizontal conductors which run each side of the roof and are kept away from it. The terminals of

Digitized by Google

the lightning rods, Mr. Hedges continued, were almost always plain spikes without branches, but German buildings had many of these both on the highest portions and along either the tops of the walls or ridge of the roof, the whole being connected together by a horizontal conductor run in the method described. A timber shed near Frankfort had these vertical rods about 15ft. apart and a petroleum storage tank at intervals all round its circumference.

The lightning conductor of the Palais de Justice of Brussels is very similar to that of the Hotel de Ville, which has been described in text-books. It is on the Melsen system, and consists of a network of metal rods connected together at the top and furnished with an aigrette or bundle of eight 4mm. copper rods spread out like a feather, so that, after passing over the roof, the terminal points project so little that they can hardly be seen from below, yet they break up the area of the buildings and leave little space unprotected. The conductors are of copper, but where they descend a special iron box is employed in which they are embedded in zinc, and from this the down rods can be continued in iron and also connected to the rain-water pipes and other ironwork of the building. The Palais de Justice was struck soon after the lightning conductor was completed, but no more damage was done than the partial fusion of some of the points of the aigrette which received the flash.

French architects, Mr. Hedges said, seem to prefer the long single point. The standard rod or *tige* is 6 metres high and about 6cm. diameter at the base, tapering to nothing at the top. The rod is firmly connected to the woodwork of the roof, and the copper or iron conductor is fixed at the base by means of a shackle. The conductor is usually kept away from the building by supports, and is carefully led into moist earth—or, in the case of rock foundations, it is connected to a network of wires running for a considerable distance under the surface. Where a well can be used, the earth connection is prepared by plaiting up galvanised iron strips to form a basket, which contains a sort of grapnel, the latter being attached to the conductor and the basket being filled with coke and lowered into the water.

The method adopted in most American cities at present, the speaker continued, is the employment of a round iron rod about half-an-inch in diameter, extending from the ridge of the metal roof about 4ft. above the top of the chimney or other elevated projection, its lower end being connected to a piece of iron in the form of a saddle, soldered to the metal roof. To this the top of each rain pipe is joined, or, where the gutters are below the roof, special tinned iron strips connect the two. It is said that each rain-water pipe 4in. diameter is equal in capacity to an iron rod $\frac{9}{16}$in. diameter. The connection between the pipe and the earth is made as follows: Above the elbow portion, a galvanised socket is fitted, and to this is soldered a flat bar which is led directly to the nearest water pipe or to the earth. The form which seems to give the best results, he said, is constructed of a pipe driven into the ground so that its perforated end rests in moist earth; its upper end is left about 6in. below the surface, so that it can be watered artificially or by rain. To assist the collection of moisture a larger sleeve is placed outside, furnished with a perforated top and set flush with the gutter. With slate or wooden roofs, bands of tin plate or galvanised iron are often placed underneath the slate covering on the rafters of the roof, being connected at the top with the "air terminal" conductors, and below with the gutters and rain-water pipes as previously described; in the case of a Mansard roof the sheet metal or flushing is also connected to the system.

Mr. Hedges was called in, in 1898, to report on the condition of the lightning conductors of St. Paul's Cathedral. He was informed that they were put up in the year 1872, having taken the place of the original system erected under the advice of the Royal Society about 144 years ago. The conductors were throughout of $\frac{1}{2}$in. stranded copper. Four of these conductors passed from the iron supports of the cross down the outside of the dome branching into eight conductors which were cross-connected by the railing of the gallery. Lower down they were united together and carried down to the ground. Each tower had two conductors with a cross connection, and there was also a single conductor passing over the ridge of the choir to an earth on either side. In the metallic connection with the cross there were several iron straps passing down inside to the level of the gallery, where the ends apparently disappeared in the stonework. This, in Mr. Hedges opinion, constituted a danger. The statues on the three sides of the building were not protected. The earth connections were also most unsatisfactory. These had originally been laid in a brick sewer passing round the building but in alterations since executed, earthenware pipes had been laid within the sewer, the brick sewer being no longer employed, and the conductors were therefore left either resting on the top of the earthenware pipe or placed within them so that they were insulated from earth. The joints were in all cases wrapped and not soldered.

The plan of re-arrangement recommended by the author, taking into consideration the large amount of copper cable already disposed about the building, was to run three new cables from the metal-work of the framework supporting the cross to the roof of the dome (making interconnection with the iron supports of the structure); there connecting them with the eight existing conductors and reuniting them at the base of the dome to the existing system, which was to be increased by running a new $\frac{1}{2}$-in. seven-ply copper cable on the top of the parapet entirely round the building. From this horizontal conductor, aigrettes, consisting of five pointed copper rods, were teed at intervals by means of special brass boxes tinned inside, into which the cable was placed, the aigrettes first secured by binding, and the whole united by running in hard solder. Great difficulty was found in securing new earths. One set of conductors was united to the hydraulic main supplying the power to the organ, and the other to the 8-in. water main. This connection was made by cleaning the outside, then wrapping the strands of the conductor around it, and then enclosing the whole in a metallic clamp which was filled with molten lead and screwed up tight. An additional earth was made by means of a perforated wrought-iron pipe furnished with a steel shoe, which was sunk to the requisite depth to secure moist ground. The stranded conductor was dropped into the pipe, soldered to a lead cap on the top, and shielded from electrolytic action by wrapping it in a lead tube. The pipe has a bend at the upper end, projecting above the ground and closed by a plug so that water can be poured down. There are other earths of ordinary copper plate buried in a mixture of charcoal and broken electric light carbons, and the old system of conductors, as well as the new, is attached to all the new earths. It is also proposed to establish connection with the ends of the rain-water pipes where they look out of the stone walls, down which all the conductors are laid.

In concluding his Paper the author repeated some of the practical suggestions with which Dr. Lodge concluded his 1889 Institution Paper (see *The Electrician*, Vol. XXIII., p. 68), adding a few suggestions of his own. He does not agree with Dr. Lodge that the use of copper is a needless extravagance, but prefers it to iron, as a lightning conductor is costly to renew and iron perishes more quickly than copper.

The Paper was illustrated by a number of excellent lantern slides, some of which had been kindly lent by the Royal Meteorological Society. These included several very interesting photographs of lightning flashes, and an excellent photograph showing the arborescent markings on the arm of a man struck by lightning.

A short discussion followed the reading of the Paper. Mr. Marriott, secretary of the Royal Meteorological Society explained, with the help of some slides, the nature of thunderstorms and the characteristic meteorological indications of their presence. Mr. Slater asked whether the hoops employed on chimneys were dangerous if not earthed, and was answered in the affirmative. Mr. Hall referred to the practice of bringing exhaust steam pipes part of the way up chimney shafts, and was told that these should also be earthed. Another speaker wished to know why a straight lightning conductor should be employed to lead away the lightning which, by the pictures shewn, appeared to prefer a wavy path. It was also elicited in the discussion that it was a dangerous practice for a man, with wet shoes, to lean against a lightning conductor during a thunderstorm.

COMPENSATION OF LINE DROP IN ALTERNATING CURRENT CIRCUITS.*

BY E. J. BERG.

To illustrate the practical application of the general equation (see footnote on next page) expressing the relation between currents and E.M.F. in an alternating-current system, assume a single-phase system in which it is desired to transmit 1,000 kw. at 60 cycles with 10,000 volts at the receiving end of the line. The length of transmission is 20 miles and the energy loss with non-inductive load about 10 per cent.; the load is, for simplicity's sake, assumed to be non-inductive. In order to determine the constants in such a system, the size of wire, the reactance, and capacity have to be calculated in the usual way. Since, however, with an overhead construction at 10,000 volts the capacity effect is very small, it can be neglected.

Line current = 1,000,000/10,000 = 100 amperes.

At 10 per cent. loss, $I^2R = 100{,}000$, thus $R = 100{,}000/10{,}000 = 10$ ohms. Therefore ohms per mile = 10/40 = 0·25, which corresponds to No. 0000 wire. This wire has 0·26 ohms per mile, therefore the resistance of transmission line is $40 \times 0{\cdot}26 = 10{\cdot}4$ ohms.

The reactance per 1,000ft. of wire is found from the following equation:—

$$x = 2\pi n \times 30{\cdot}5 \times 10^{-6}(2\log_\epsilon 2L/d + \tfrac{1}{2}),$$

where x = reactance per 1,000ft. of wire, m = frequency, L = distance between wires, d = diameter of wire expressed in same units as the distance. Assuming 18in. distance between wires, we get—

$$x = \frac{5{\cdot}28 \times 40 \times 2\pi 60}{10^6} \times 30{\cdot}5\left(2\log_\epsilon \frac{36}{0{\cdot}46} + \tfrac{1}{2}\right) = 22{\cdot}5 \text{ ohms.}$$

Impedance of line is $z = \sqrt{10{\cdot}4^2 + 22{\cdot}5^2} = 24{\cdot}8$ ohms.

* From the *Electrical World* of New York.

Digitized by Google

The generator voltage at non-inductive load is obtained directly from equation (A), or

$$e_0 = \sqrt{(e+ir)^2+i^2x^2} = \sqrt{(100{,}000+100\times 10{\cdot}4)^2+100^2\times 22{\cdot}5^2}. \quad (D)$$

or the generator has 13 per cent. higher voltage than the receiving end of the line, with 10·4 per cent. energy loss and no compensation of line drop.

If it is desired that the generator voltage and the voltage at the receiving end shall be the same—that is, to compensate for the entire line drop—the value of i_3, the leading current, is obtained directly from equation (C) and is

$$i_3 = 10{,}000\times 22{\cdot}5 - \sqrt{\frac{(225{,}000)^2}{615} - 100^2 - \frac{2{,}000{,}000\times 10{\cdot}4}{615}}$$

$= 66$ amperes, or 66 per cent. of the full load energy current.

In other words, the condenser should be of such size that it will take 66 amperes when connected across the 10,000 volt mains, or be of 660 kw. capacity. Since a synchronous motor can be used as condenser by over-exciting its field, a synchronous motor can be substituted for this condenser. Such synchronous motor should have a current capacity of 66 amperes, and be wound for a potential of 10,000 volts—that is, it should also be of 660 kw. capacity. Its field should be so much over-excited that while running light—that is, carrying no load—its current should be 66 amperes.

If there is no margin in current capacity, it is possible to put any mechanical load on the motor and at the same time obtain this potential control. Were there, however, only a slight margin, considerable load could be carried. For instance, if the current capacity were 5 per cent. larger, or 69·3 amperes, the motor could carry a load corresponding to 21·2 amperes or 212 kw., as obtained from the diagram of Fig. 1. With 10 per cent. increase in current capacity a load of 303 kw. can be carried, and with 15 per cent. increase in current capacity a load of 375 kw. That is, with 5 per cent. increase in current over that necessary to obtain phase control a load of 31·6 per cent. of the synchronous motor rating can be carried; with 10 per cent. increase in current a load of 45 per cent., and with 15 per cent.

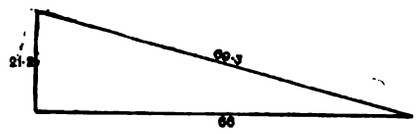

FIG. 1.—Relation of Currents.

a load of 56·6 per cent. of the synchronous motor rating can be carried. Or, vice versa, if a fully loaded synchronous motor is available in a system where phase control is desired, a compensation of lagging currents of 31·6 per cent., 45·8 per cent., and 56·6 per cent. respectively of the current capacity of the motor can be obtained by over-exciting the motor so as to take 5 per cent., 10 per cent., and 15 per cent. respectively more than full load current.

Such synchronous motor acts within a fair limit as an automatic compensator, since as the load increases the line drop increases—that is, the voltage at the motor terminals decreases—and therefore, if excited from a source of constant potential, and thus giving constant counter E.M.F., it takes more and more leading current, which is desirable. Since, however, this feature depends upon the armature reaction and magnetic condition—that is, the saturation of the motor—it is impossible to deal with it except in each particular case. As stated above, however, the control is often close enough without change of excitation of the motor: at the same time, if perfectly constant voltage is desired, the excitation has to be increased with the load.

If it is desired to have the synchronous motor over-excited so as to make the receiving voltage 5 per cent. higher than the generating voltage, the corresponding value of wattless current i_3 is obtained from the same equation (C) by substituting for $e_0 = 0{\cdot}95e$, as follows:—

$$i_3 = \frac{225{,}000}{615} - \sqrt{\frac{(225{,}000)^2}{615} - 100^2 - \frac{2{,}000{,}000\times 10{\cdot}4}{615} - \frac{10{,}000{,}000}{615}}$$

$= 95$ amperes.

That is, the wattless leading current is 95 per cent. of the full load energy current. In other words, a compensator or synchronous motor of 95 per cent. capacity of the load would be necessary to accomplish this.

The distribution of potential along the line in such a system can be obtained by considering the generator placed in the various points under consideration; in other words, by solving the equation by inserting proper values of r and x corresponding to distances between receiving station and the point of the line under consideration. Thus,

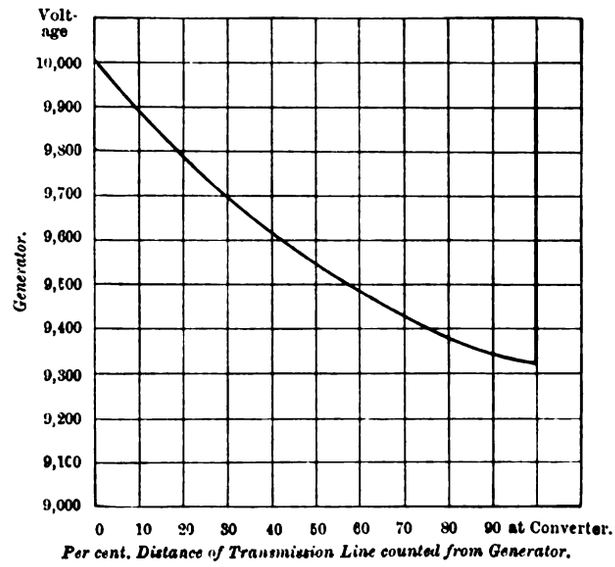

FIG. 2.—Distribution of Potential along a Line of 10·4 ohms resistance and 22·5 per cent. reactance with 15 per cent. additional reactance at Converter.

for instance, in the first case, when the voltage at generator and receiving end of the line is the same, at one-quarter of the distance counted from the receiving station, $r = 10{\cdot}4/4 = 2{\cdot}6$, $x = 22{\cdot}5/4 = 5{\cdot}62$.

$$e_0 = \sqrt{z^2(i_3^2+i^2) - 2e(i_3x - ir) + e^2} \quad \ldots\ldots\ldots \quad (E)$$

$$= \sqrt{38{\cdot}3(4{,}350+10{,}000) - 20{,}000(370-260) + 100{,}000{,}000}$$

$= 9{,}925$ volts.

In a similar way, by inserting other values for r and x, the following table has been calculated:—

Distance from receiving station.	e_0.	Distance from receiving station.	e_0.
0·1	10,000	0·6	9,880
0·2	9,930	0·7	9,900
0·3	9,900	0·8	9,920
0·4	9,880	0·9	9,950
0·5	9,880	Generator	10,000

It is of interest to note that the voltage all along the line is less than at the generator and at the receiving circuit; also that the percentage drop in voltage at any particular point is very small compared with the percentage line loss. In other words, for practical purposes the line has *practically* constant potential all over.

It is often advisable to instal special reactances in series with the line at the receiving end, in order to obtain more total reactance than that available in the line itself, and thereby to lower the wattless current necessary for phase or potential control. For instance, if reactive coils of 15 per cent. capacity of the load were installed, the wattless current under the condition given—the same voltage at

---

The general equation giving relation between currents and E.M.F.s in an alternating current system is expressed in complex quantities in equation (A):—

$$E_0 = E + (i+ji_1)(r-jx)$$

where

E_0 = generator voltage,
E = voltage at receiving end of transmission,
i = energy component of current,
i_1 = wattless component of current, which may in its turn be expressed as $i_2 - i_3$, where i_2 is the lagging component and i_3 the leading component;
r = resistance of transmission line,
x = reactance of transmission line.

This equation is essentially the same as in a direct-current circuit, and consists of three terms: The first, the E.M.F. generated; the second, the E.M.F. at the receiving end; and the third, the drop in voltage in the line. The only difference is that in an alternating-current circuit the drop is expressed as:—

$$(i+ji_1)(r-jx),$$

whereas in a direct-current circuit it is simply ir.

Solving equation (A) in reference to i_1, the wattless component of current, and substituting the real values of E_0 and E as e_0 and e we get

$$i_1 = \frac{-ex}{z^2} \pm \sqrt{\frac{e^2x^2}{z^4} - \frac{2eir}{z^2} + \frac{e_0^2 - e^2}{z^2}}. \quad \ldots\ldots \quad (B)$$

With non-inductive receiving circuit i_2 is zero and $i_1 = i_3$ thus represents the leading or condenser current.

$$\text{Thus } i_3 = \frac{ex}{z^2} - \sqrt{\frac{e^2x^2}{z^4} - i^2 - \frac{2eir}{z^2} + \frac{e_0^2 - e^2}{z^2}} \quad \ldots \quad (C)$$

neglecting the + sign for the square root since the value corresponding thereto is of no practical value.

This last equation enables us to calculate how much leading current is necessary in order to obtain any desired relation between the generator voltage and the voltage at the receiving end—that is, between e_0 e, in systems of non-inductive receiving circuit.

Digitized by Google

the receiving end and the generating end—would be 54 amperes instead of 66 amperes, as can readily be obtained by inserting $r=10{\cdot}4$; but for $x=22{\cdot}5+15=37{\cdot}5$ ohms, as follows :—

$$i_3=\frac{375{,}000}{1{,}513}=\sqrt{\frac{(375{,}000)^2}{1{,}513}-10{,}000-\frac{2{,}000{,}000\times 10{\cdot}4}{1{,}513}}$$

$=54$ amperes,

which shows that by the introduction of 15 per cent. reactance the condenser current is decreased 18 per cent. in this case. In general, the more reactance the lesser condenser current, or the more reactance the smaller synchronous motor is required for controlling the voltage. The condenser current necessary to give 5 per cent. over-compounding is found by the same equation when substituting $e_0=9{,}500$, $e=10{,}000$. This gives $i=73$ amperes, or 23 per cent. less than when no additional reactance is used.

Before leaving this problem it is of interest to see directly the effect of reactance on the amount of condenser current. By substituting various values of x in equation (C), the corresponding values for i_3 are set out in the following table :—

x.	i.	x.	i.
10	133	50	54·5
20	72	60	59
30	57·5	70	66
40	54	80	80

This effect of reactance is clearly shown in Fig. 3.

Briefly, there is a certain most favourable amount of reactance which corresponding to minimum current and minimum size of

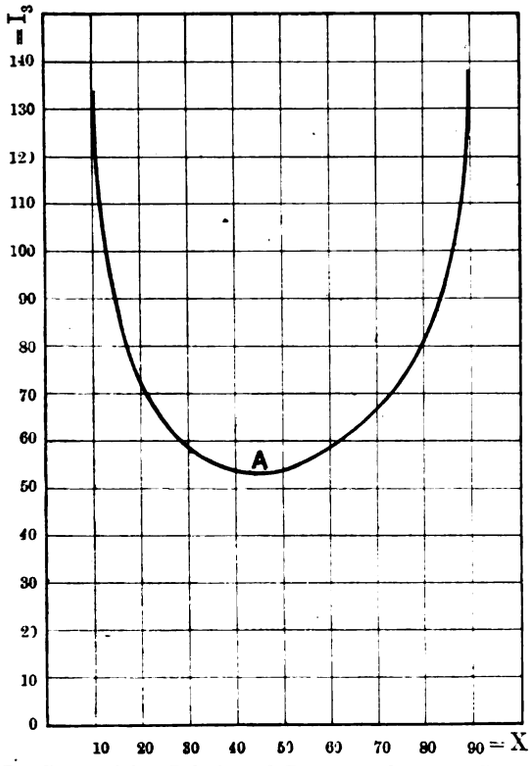

FIG. 3.—Curve giving Relation of Reactance between Generator and Receiving Circuit, and condenser current to give same potential at generator and receiving circuit in a system of 10·4 per cent. resistance loss at non-inductive load.

synchronous motor, and which gives minimum line loss. In general, when line drop is compensated for in systems of non-inductive receiving circuits, the line loss is increased. In this particular case, although with non-inductive load the loss is only 10·4 per cent., it is with various reactances as follows :—

Reactance.	Loss.	Reactance.	Loss.
10 per cent.	30 per cent.	50 per cent.	14 per cent.
20 do.	16 do.	60 do.	14·5 do.
30 do.	14 do.	70 do.	15·5 do.
40 do.	12 do.	80 do.	18 do.

It is frequently not advisable to insert too much reactance between the generator and synchronous motor, since the stability of the system is affected thereby. In these cases it may seem strange that so great an amount of reactance and leading current is necessary to compensate for 10 per cent. drop. The reason is that the maximum output of the line is approached. A much less amount would have been required if the generator was kept at 10 per cent. higher voltage at all loads—that is, if the potential at the generator had been 11,000 volts at all loads and that of the receiving end 10,000 volts. Such a condition could have been obtained by under-exciting the synchronous motor at no load. The distribution of potential along the line in such installations with reactive coils at the receiving circuit can be obtained in same manner as above by solving equation (A) with reference to e_0 as follows :—

$$e_0=\sqrt{z^2(i_3^2+i^2)-2e(i_3x-ir)+e^2}.$$

Fig. 2 is calculated by inserting for $e=10{,}000$, $i=100$, $i_2=51$, at generator $r=4$, $x=37{\cdot}5$.

Distance from generator.	r.	x.	Distance from generator.	r.	x.
0·1	9·36	35·3	0·9	1·04	17·2
0·2	8·32	33·0	Converter (line side of reactive coil)	0	15·0
0·3	7·30	30·8			
0·4	6·25	28·5			
0·5	5·2	26·3			
0·6	4·16	24·0	Converter (bet. reactive coil and collector)	0	0
0·7	3·12	21·75			
0·8	2·08	19·5			

From this curve it is seen that the voltage rises abruptly across the reactive coil; it is lower than the voltage at the receiving end and generating end all along the line; it gradually rises from the reactive coil up to the generating station, and rises at once across the reactance to the proper value. The drop in voltage in any point of the line is less than corresponds to the ohmic drop.

The real advantage of synchronous motor phase control is, however, first apparent in systems with inductive receiving circuits. Referring back to equation (B) and substituting for $i_1=i_2-i_3$, we get :—

$$i_3=i_2+\frac{ex}{z^2}-\sqrt{\frac{e^2x^2}{z^4}-z^2-\frac{2e\,ir}{z^2}+\frac{e_0^2-e^2}{z^2}} \quad . \quad . \quad . \quad (F)$$

In the above numerical instance assuming the power factor of the load to be 90 per cent., $i=100$, $i_1=\sqrt{114^2-100^2}=48$. The gen-

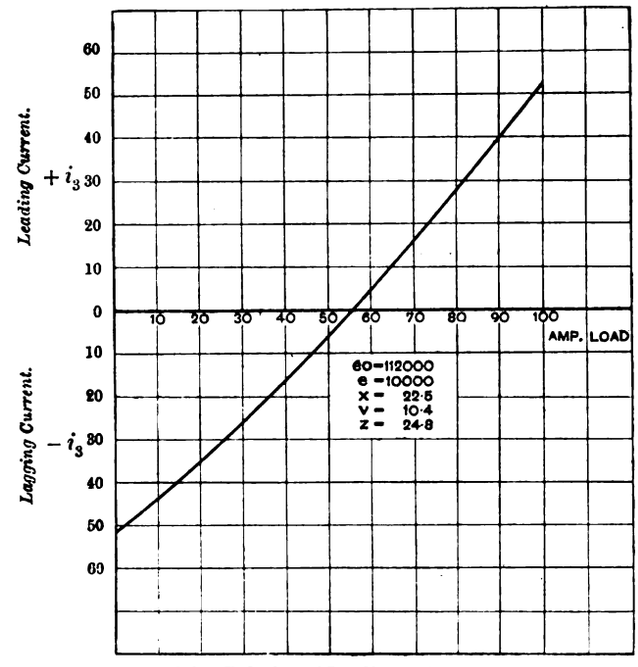

FIG. 4.—Curve giving Relation of Leading and Lagging Current, taken by synchronous motor as function of load of the receiving system. Generator voltage kept constant at 112,000 volts, voltage at receiving end of line 10,000 volts at all loads.

erator voltage is obtained by solving equation (A) with reference to e_0 as follows:—

$$e_0=\sqrt{(e+ir+i_1r)^2+(ix-i_1r)^2} \quad . \quad . \quad . \quad . \quad . \quad (G)$$

substituting for $e=10{,}0000$, $i=100$, $i_1=48$, $r=10{\cdot}4$, x $22{\cdot}5$, e_0 is found to be 12 200 volts. Or thus the generator voltage is 22 per cent. higher than the voltage at the receiving circuit. The energy loss in the line is $(100^2+48^2)\times 10\,4=128{,}000$ watts, or 12·8 per cent. of the delivered power. In such a system it would be well to keep the generator voltage about 10 per cent. higher than the voltage of the receiving end at all loads; in other words, to keep e_0 = about 11,000 and $e=10{,}000$ at all loads. Furthermore, the synchronous motor has to take lagging currents at light loads and leading currents at full load. Neglecting the small energy current necessary to run the synchronous motor light at non-inductive excitation, and assuming that the nature of the load remains the same at all loads—that is, its power factor remains the same—we have $i_2=0{\cdot}481$. Assuming further $e_0=11{,}200$ volts, $e=10{,}000$ volts, and substituting these values in equa-

Digitized by Google

tion (G) and solving with reference to i, it is found that $i_2 = 52$ amperes, or at 52 per cent. of rated load no phase control is exerted. At no load the synchronous motor should take 52 amperes lagging current, and at full load 52 amperes leading current. In other words, the capacity of the synchronous motor is just about 50 per cent. of the load. The amount of current taken by the motor at all loads is shown in Fig. 4. As will be seen, the synchronous motor should run non-inductively at 54 per cent. of full load of the system. Without the use of a compensator the full load line current is 111 amperes, therefore the loss is $111^2 \times 10{\cdot}4 = 128{,}000$ watts, or 12·8 per cent. of the delivered power With the synchronous motor the line current is 100 amperes, and the loss therefore only 104,000 watts, or 10·4 per cent. The poorer the power factor of the load, the more advantageous it is to use this method of potential control.

In conclusion, it may be brought out once more that although a non-inductive receiving circuit has been considered chiefly in the present instance, this method of compensation of drop is not well suitable except in cases where the load is more or less inductive, or when it is desired to have the voltage constant and the same all along a line. It is hardly desirable to try to maintain the same generator voltage as the voltage at the receiving end, or to get a higher voltage at the receiving end than at the generator, unless there is no objection to large reactances and comparatively large wattless currents. It is, however, perfectly feasible to maintain the generators at a somewhat higher voltage than that at the receiving end at all loads; in other words, to lower the voltage by means of under-exciting the synchronous motors, which causes them to take lagging current at no load, and to run them under non-inductive condition at part of the load and with leading currents at full load. Under these conditions, the amount of reactance, leading current, and boosting the voltage can be comparatively closely approximated as follows: With 10 per cent. reactance and full load leading current 10 per cent. boosting of voltage is obtained. With 20 per cent. reactance and full leading current 20 per cent. boosting is obtained. With 10 per cent. reactance and one-half full load leading current 5 per cent. boosting is obtained. With 20 per cent. reactance and one-half full load leading current 10 per cent. boosting is obtained, &c. This rule holds comparatively good unless the maximum output of the line is approached, as is the case in the examples assumed. The chief advantage of the synchronous motor used as compensator is, however, to be found in systems of lagging currents, such as induction motor installations, where the drop in the line and the current in the line are larger than at non-inductive load. In such case not only is the efficiency of the system raised, but the line loss is lessened; whereas with non-inductive load the line loss is increased by the use of synchronous motors or potential control.

LEGAL INTELLIGENCE.

National Co. for the Distribution of Electricity, &c., Ltd. v. Gibbs and another.

In the Court of Appeal on Tuesday and Wednesday, before the Master of the Rolls and Lords Justices Rigby and Collins, this case was heard on appeal by defendant, H. O. Ruelle, from an order of Mr. Justice Cozens-Hardy. There was also a cross appeal by the plaintiff company from the same order.

Mr. EVE, Q.C., for the defendant, said the learned judge had dismissed both the action and counterclaim, and his client only appealed from that part of the order which dismissed the counterclaim. The action was brought claiming damages for breach of an agreement, and the counterclaim sought to enforce a judgment which had been obtained in France in an action between the same parties. The point which the learned judge decided was that the grant of letters patent in the ordinary form to two persons, their executors, administrators and assigns, constituted them joint tenants, and that the benefit of letters patent survived to the survivor, and accordingly that the legal personal representative of one of the joint grantees could not be sued in respect of the assignment of the patents, and could not herself sue in respect of royalties. The plaintiff company was in liquidation. It was incorporated in 1883 for the purpose of acquiring from Messrs. Gaulard and Gibbs the benefit of certain letters patent which they had obtained in respect of apparatus for the distribution of electricity by means of secondary generators. The agreement was dated May 25, 1883, and was between Lucien Gaulard and John Dixon Gibbs and the company. After reciting the consideration to be paid, Clause 7 of the agreement provided that the said vendors and all other necessary parties should, with the consent of the company, execute such assignments to the company or as they should direct, and such assignments respectively should contain a covenant by the said vendors that all the letters patent thereby assigned were valid and in nowise void or voidable. The action was brought upon these covenants, the case of the company being that the British patents were not valid, and that, so far as other countries, including the United States, were concerned, they were limited in their application. They consequently claimed damages to a large amount. As regarded the survivor Gibbs, the action was compromised, and it therefore went on against Madame Ruelle as the legal personal representative of the deceased grantor Gaulard. By way of counterclaim the defendant Ruelle set up a judgment of the Paris Court of Appeal, under which, after protracted litigation, the company were held liable to pay to her a sum of £2,600. By way of defence to the action the defendant alleged that all the matters in dispute had been determined in the French proceedings, and that the release of Gibbs *pendente lite* was a release for the deceased man.

After hearing the arguments on both sides,

The MASTER OF THE ROLLS said in this case he was unable to agree with the view adopted by the learned judge, but he doubted very much whether the practical result of the view they had adopted would be more beneficial to the parties. There were two patentees—Gaulard and Gibbs—who were entitled to certain patents for the distribution of electricity, and they agreed to sell them to the plaintiff company under an agreement dated May 25, 1883. The learned judge had treated this agreement as neither more nor less than a joint covenant by Gaulard and Gibbs to assign these patents with a covenant of title, and he decided the case upon the short ground that Gaulard being dead there was no remedy against his personal representative, and that the claim therefore of the company against her failed. If the company could therefore only look to Gibbs it followed that the defendant's counterclaim against the company also failed. By taking that short cut the learned judge dismissed both the action and counterclaim. He could not think that that view was correct, and what the Court proposed to do was to reverse the judgment, and declare that upon the true construction of the agreement the right of the plaintiff company for relief against Madame Ruelle was to be ascertained upon the footing that Gaulard and Gibbs had jointly covenanted to assign the patents mentioned in the agreement to the plaintiff company, and that such assignments should contain joint and several covenants that such patents were valid, and in no wise void or voidable. Then a declaration that the amount due from the company to Madame Ruelle on her counterclaim was to be ascertained upon the footing of the order made on the proceedings in the French Courts, and with these declarations to remit the action and counterclaim for trial. They proposed to reserve the question of the costs of the action and counterclaim and of the appeal, including the costs of the plaintiffs' cross appeal, to be dealt with by the judge at the trial. A point had been raised that the plaintiffs' appeal was out of time, and that it had reference to a separate and distinct cause of action, but the learned judge had so linked the action and counterclaim together that they did not think they ought to be debarred on that ground. He thought counsel would do well to advise their clients to see whether they could not settle their differences by compromise, and so avoid further litigation.

Kirby v. Lawson.

This case came before Mr. Justice Grantham and a special jury in the Queen's Bench Division on Tuesday, and was an action to recover £2,000 commission alleged to be due from Mr. Harry J. Lawson, a company promoter.

Mr. RUFUS ISAACS, Q.C., said that the plaintiff, Mr. Frederick Kirby, was a civil engineer and was associated in business with a Mr. Wells. In June last year, Mr. Lawson had some business in hand in connection with a then projected company, to be called the Electrical Tramways Construction Co., and he desired an introduction to an engineer of considerable eminence in the electrical world whose name could appear on the prospectus. In an earlier matter Mr. Kirby had introduced to the defendant Sir William Preece, for which service he received a commission. The subject was introduced to plaintiff and Mr. Wells by Mr. Tom Lawson, brother of defendant, and as a result, the three met Mr. H. J. Lawson. After some negotiation defendant promised verbally to pay £2,000 commission for the introduction to Mr. Thomas Parker, an electrical engineer of established reputation, who had been described by Lord Kelvin as the "Edison of Europe." The introduction was duly effected, and there was an agreement drawn up between Mr. Parker and the company. Mr. Lawson now denied having made any undertaking to pay the commission.

Mr. FREDERICK KIRBY, the plaintiff, said he had originally asked for £5,000 as commission for the introduction of Mr. Thomas Parker, but that finally £2,000 was agreed upon, and Mr. Parker, who was then waiting at the Hotel Cecil, was duly introduced to Mr. H. J. Lawson. He did not know Mr. Lawson had previously been introduced to Mr. Parker in connection with automobile business, and it was not the fact that the commission was only to be paid on Mr. Parker consenting to come into the business and to accept the post of consulting engineer to the Electrical Tramways Construction Co. at a salary of £1,000 per annum. He pointed out to Mr. H. J. Lawson that if he got hold of Mr. Parker the latter would doubtless obtain for the new company the order for the electrical equipment of the Metropolitan Railway, and influence the necessary financial assistance, and so make the business of the Electrical Tramways Construction Co. the finest in existence. Mr. Parker had, however, declined to execute an agreement with the Electrical Tramways Construction Co. unless the latter took over some part of the Wolverhampton business with which he was associated.

Mr. MARSHALL HALL, Q.C., said plaintiff and his colleagues originally wanted to get Mr. H. J. Lawson to take up Mr. Thomas Parker and his Wolverhampton business on a commission to them of £5,000, but that had been declined. It was proposed that the new company should start a factory for the purpose of making electrical tramway plant. Mr. Lawson was himself anxious to get a first-class scientific man like Mr. Thomas Parker at the head of it, and on the terms that Mr. Parker should come in at £1,000 a year salary, and bring his influence, he offered the present claimants £2,000 commission, as and when the company was formed, because they had represented that Mr. Kirby had influence with Mr. Parker, and could persuade him to join the company. It was idle to suggest that Mr. Lawson would pay £2,000 for merely bringing the people into one room. Mr. Parker had always refused the appointment with the Electrical Tramways Construction Co. unless his

Digitized by Google

businesses were taken over, and for that reason the agreement had never been completed.

Mr. H. J. LAWSON was called, and said he was still engaged on the scheme for electrical tramways construction. Mr. Parker was known to him before this introduction. Mr. Kirby represented himself as an old personal friend who could persuade Mr. Parker to join in the scheme as consulting engineer and director, and give his influence to the company. At the interview the witness refused to give a commission note or to be bound in any way, telling the plaintiffs they must depend entirely on how he got on. That was the usual thing, and he always worked on those terms. He had not been able to make any agreement with Mr. Parker, but if Mr. Kirby would get that gentleman to execute the agreement now he would pay him the £2,000 claimed.

In the result the jury found for defendant, and judgment was entered accordingly.

Alleged Electricity Supply Failures.

At the Greenwich Police Court, on Tuesday, the London Electric Supply Corporation appeared to seven adjourned summonses at the instance of a publican (occupier of the Dover Castle public house, Deptford) for making default in supplying electric energy. Mr. Lawless, for complainant, said his client had spent £200 in having his premises wired and fitted, and the defendants, during the winter neglected to supply Deptford while they were supplying the West End, the result being his client's public house was left in darkness from 4 o'clock to 8.30. Mr. Bailhache, for the Corporation, admitted the failure, and quoted the Electric Lighting Orders Confirmation Act to show that the company was not responsible for failure due to inevitable accident or *force majeure*. The latter was foreign to English statute, and if the magistrates should be against him he must ask for a case.

The Managing Director, (Mr. R. Stewart Bain) detailed the difficulties the company had laboured under through the failure of contractors to supply boilers to time, as well as to explosions of tubes, which necessitated the withdrawal from use of five or six boilers. The coal supply had also been a cause of difficulty. Mr. Lawless argued that *force majeure* did not apply in this case, and the magistrate (Mr. Kennedy) said he would give his decision on May 4.

On the same day at Southwark the same company were summoned at the instance of the London County Council for failing to maintain a proper supply of electric current in their mains adjacent to 148, Borough High-street, the Weights and Measures Office, Union-road, and St. George's Public Library, Borough-road, on various dates in January and February, and further for making default in supplying current to the same premises. The magistrate (Mr. Paul Taylor) said that no evidence had been given to show negligence on the part of the company. Yet even if there was slight neglect it seemed, in the circumstances, to be covered by the term *force majeure*. If it was contended that want of foresight was negligence, how could it be said that the company could have foreseen the failure of contractors to provide boilers?; or, that the company could have foreseen that the South African war would cause a shortage in the supply of Welsh steam coal? He had decided to dismiss the summonses.

At Marylebone the Metropolitan Electric Supply Co. appeared before Mr. Plowden to answer six adjourned summonses, at the instance of the Marylebone Vestry and the Marylebone Guardians, for in December making default in the supply of electric energy. When the case was originally heard, Mr. Muir (for the company) pleaded guilty, and offered an explanation in mitigation. He said that measures had been taken to prevent a recurrence of the cause of complaint, and asked, as a test, that the case should be adjourned for three months. Mr. Neill (for the prosecutors) now stated that during January, February and March there had been 14 occasions on which the company had failed in its supply. Mr. Muir said that there had been no repetition of the original faults, and that the failures since had been beyond human foresight. The plant was tested every day. Mr. Plowden thought the explanation as to the failures this year exculpated the company. On the original summonses they would have to pay 5s. for each date (total £1 5s.), with costs.

FORTHCOMING LEGAL ACTIONS.

Causes with an electrical interest entered for hearing at the Royal Courts of Justice during the Easter Sittings, 1900, include the following:—

SUPREME COURT OF JUDICATURE.—COURT OF APPEAL.

From Chancery Division.

The Electric Construction Co. (Ltd.) *v.* Imperial Tramways Co. (Ltd.). (British Thomson-Houston Co. (Ltd.) third parties). (Appeal of plaintiffs from order of Mr. Justice Cozens-Hardy, dated Nov. 14, 1899.)

Heyl-Dia *v.* Edmunds. (Appeal of plaintiff from order of Mr. Justice Kekewich, dated November 11, 1899.)

British Motor Syndicate (Ltd.) *v.* John Taylor and Sons (Ltd.). (Appeal of defendants from order of Mr. Justice Stirling, dated Feb. 15, 1900.)

Rucker *v.* The London Electric Corporation (Ltd.). (Appeal of plaintiff from order of Mr. Justice Farwell, dated Feb. 12, 1900.)

QUEEN'S BENCH. Final Appeals.

The Mayor &c. of the Borough of Hyde, Oldham, and Ashton *v.* Hyde Electric Tramway (Ltd.), and others. (Appeal of Defendants from judgment of Mr. Justice Grantham, dated July 3, 1899; at trial without a jury.)

QUEEN'S BENCH DIVISION.—*Special Juries.*

A. Shanks and Son (Ltd.) *v.* the Globe Electrical Co. (Bill).

Stephens *v.* Mather and Platt. (Commission).

Revenue Paper.

ttorney-General *v.* National Telephone Co.

CHANCERY DIVISION.

Before Mr. Justice Stirling.

Cuba Submarine Telegraph Co. (Ltd.) *v.* the West India and Panama Telegraph Co. (Ltd)

Before Mr. Justice Farwell.

Chamberlain and Hookham *v.* Mayor, &c., of Bradford.

City of London Electric Lighting Co. *v.* Corporation of London (ordered to stand over till May 21.)

Jandus Arc Lamp and Electric Co. (Ltd.) *v.* Johnson (action and counterclaim).

MUNICIPAL, FOREIGN & GENERAL NOTES.

Alleged Incendiarism.—At the West Ham Police Court on Saturday an electrical wireman named Christian Maddock was charged with attempting to set fire to a building and its contents at the India Rubber, Gutta Percha and Telegraph Works Co.'s factory, Factory-road, Silvertown. Mr. F. Stern, who prosecuted, said a serious conflagration had apparently been escaped only by reason of the carefulness of an employé. There had been six fires at this factory during the last twelve months, and though it could not be suggested that prisoner was connected with them, in view of the charge now made against him the fact could only be regarded as remarkable. Alfred May, storekeeper at the factory, deposed that on the previous afternoon he was in the pattern shop in which were stored some 18,000 wood patterns. He had had two visits from the prisoner, and his conversations aroused witness's suspicions, and he concealed himself. Prisoner went to the spot where they had previously stood and took up a pattern—a disc-shaped piece of wood like a flower-pot saucer. He put the "saucer" by the side of a box and then left the room. Going to the spot witness found that the pattern contained about three-quarters of a pint of methylated spirit, and he then called Mr. Kennedy's and Mr. McNault's attention to the matter. Methylated spirit was not used in the store, which was lighted by electricity. No unmasked lights were used there. John Pattison, a foreman, deposed that he went to the pattern room after Mr. May had created an alarm. He put on a temporary electric light, and saw the box produced turned mouth downwards. Beneath the box he found a candle stuck in a bit of wood. The wood was partially covered with cotton-waste, and the cotton-waste was soaked with methylated spirit. Across the waste was a ginger beer bottle, which was uncorked and half filled with methylated spirit. The candle had been freshly trimmed and was ready for lighting, and a piece of its wax was lying close by. Around about the floor of the room was wet and smelt of spirit. Prisoner would use spirit and waste in his work. Constable Green deposed to arresting prisoner, who said: "Someone has made a big job of this for me; I did not think it would come to this. Will it be settled by a magistrate or go to the Old Bailey?"—Remanded.

Barrow-in-Furness.—The accounts for the electricity department for the year ended March 31 have been issued. The capital expenditure is nearly £33,000, the revenue for the year £2,600, and the annual expenditure £1,900, leaving a gross profit of £750. It has been decided to make a reduction in the charge for current.

Brussels-Antwerp Electric Railway.—A bill has been introduced in the Belgian Chamber of Deputies to authorise the construction of this railway. The concession for the line, which will be for 60 years, has not yet been granted. The Government reserve the right to acquire the line at ten years from date of opening, and, among the other conditions, the concessionaires will have to contribute one-half of the net loss in receipts which may arise on the existing State railway between Brussels and Antwerp.

Calcutta.—An electric lighting installation was recently erected at the Government House by Messrs. Balmer, Laurie and Co.

Cardiff.—At the meeting of the Lighting committee, on Friday, applications for the position of mains superintendent were considered, and Messrs. H. D. B. How, of London, E. Jones, of Cardiff, and W. H. Illingworth, of Halifax, were chosen, from whom a final selection will be made at the next meeting of the committee.

At the end of March the equivalent number of 8 c.p lamps connected was 27,463, compared with 21,782 last year, and there were 1,512 lamps awaiting connection. The number of units sold was 509,000, against 405,000 units in the preceding 12 months, an increase of 25 per cent. The increase in revenue was £1,500.

A special meeting of the Council was held on Monday to consider the supply of electric current for the projected system of electric tramways. The Tramways committee recommended the erection of a separate station for tramway purposes, but Ald. Carey, chairman of the Lighting committee, moved that the Council adopt a combined station. He said nearly all municipalities in this country which had considered this question had favoured combined stations, and contended that whatever could be done by the Tramway committee the Lighting committee could most successfully carry out. If the Corporation erected a separate station they must have extra land, extra buildings, and an additional staff, whereas the present lighting station,

Digitized by Google

with certain alterations, could run a large portion of the trams in Cardiff. The Tramway committee had scheduled land for stations at Roath, Portmanmoor-road, Cathays, and Clare-road, which were most of them as far from the centre of the town as the lighting station. The Lighting committee had expended £85,000 upon their station, and had authority to spend an additional £12,000. The capacity of the station was 60,000 units per annum, and at present they supplied 30,000 units, and as new applications for 10,000 a year were coming in the committee would have to look out for another station during the next few years. They supplied current to the public arc lamps at £18 per annum, which worked out at 1·7d. per unit, although the cost of generation was 2·16d. per unit. They lost, therefore, ½d. per unit, which amounted to over £200 per annum. This charge of £18 per lamp at Cardiff compared with £32 at Bristol, and £20 at Edinburgh. The cost of generating had been reduced from 3·1d. per unit in 1895, to 2·16d. in 1898. The Lighting committee certainly deserved some consideration for the work they had done. Mr. T. Andrews, chairman of the Tramways committee, moved that a separate station be erected as a distinct undertaking. He quoted from the report of the Huddersfield borough engineer (Mr. Campbell) who favoured an independent station, and who had stated that on no consideration should sub-stations or accumulators be provided if tramway equipment was to consist of the best and most up-to-date plant. His committee wanted to know what price the Lighting committee would charge for current; that was the crux of the whole question. Altogether they would ultimately have to work 26¼ miles of tramway by electric traction. That was a large order, and the present lighting station was totally unsuitable for electric traction plant. If electric traction was to be a success they must have a separate station. The erection of a large power station would require the attention of a first-class electric traction engineer, a permanent official to design and superintend the erection of the station and advise the committee as to the machinery and plant necessary. This man should be engaged immediately and be held responsible. In towns where energy was purchased from the Lighting committee the charge was very much higher than it could be produced by the Tramway committee themselves. He pointed out that current for tramways would be required for 16 hours out of 24, whereas the lighting was only required for six hours per day, and he did not see why the greater should be subject to the smaller undertaking. He had hoped that Ald. Carey would have been able to put forward some alternative scheme that he would be able to offer power at, say, ¾d. per unit, but he had not done that. Eventually the debate was adjourned until May 7, and both committees are to submit additional information.

Dundee.—The Lighting committee have considered reports from the city electrical and gas engineers regarding the proposed extension of the electric lighting system. It was stated that the annual cost of lighting the tram routes by gas would be £348. 0s. 4d., and by electricity (lamps being placed in the centre and side of the streets) the initial cost would be £1,730, and the annual upkeep £1,138. 18s.

East London Electric Lighting Orders.—The Board of Trade have intimated to the Vestries of St. George's in the East and Mile End Old Town and the District Board of Works of Limehouse that they propose to grant the applications of these local authorities for provisional orders. The applications were opposed by the County of London Co., who already possess electric lighting powers for these districts, and particulars of the conference which took place at the Board of Trade in connection with the matter will be found in our issue of March 30.

At the meeting of the Mile End Old Town Vestry last week it was reported that amended plans and notices had been received from the County of London Co. giving notice of intention at the expiration of one month to commence the execution of works under their provisional order. The Electric Light committee reported they saw no objection to the plans submitted, but after discussion it was decided to refer the report back.

Edinburgh.—The Council have decided to erect 72 additional arc lamps for street lighting. At the Council meeting on Tuesday, the convener of the Electric Lighting Committee (Bailie Mackenzie) said he had received a report on the approximate cost per lamp from the electrical engineer as follows:—Carbons £1. 2s. 6d.; coal, £3. 5s. 0d.; stores, 6s.; trimmers' wages, £3.; maintenance, £1. 7s.; interest and sinking fund, £2. 17s.—total, £11. 17s. 6d. The rise in the price of coal for the coming year would represent £1. 1s., and for carbon, 7s. 6d.—making a total cost per lamp of £13. 6s. With the 72 lamps proposed, the total number of lamps would be 839, which, at 6s. per lamp, would mean a loss on the year of £251. 14s. They had, however, only made coal contracts for three months. Even supposing they made a loss of 6s. per arc lamp, he was in favour of going on with the extension, because the general community got the benefit of the light, and the public lighting was a good advertisement for the private lighting. The Electric Light committee has been requested to report upon the charge to be made for electric current for the year commencing May 15, and also on the expediency of the Corporation hiring out electric motors in order to increase the day load.

Fatal Accident.—An inquest was held at Blackpool last week into the death of J. A. Hopton, electrician, engaged on the local electric tramway. Hopton, it appeared, attempted to board a car from the front, and was crushed between the tram and the pole. It was stated in evidence that it was the custom of the electricians to ride upon the front of the car in order to be out of the way of passengers. The town clerk explained that a bye-law had been in force prohibiting anybody from entering the front of the car while in motion. A verdict of accidental death was returned.

Fire Prevention.—The British Fire Prevention committee, presided over by Mr. Edwin O. Sachs, is discussing the question of obtaining some international basis for tests with fire-resisting materials with a view to arriving at comparative results. Mr. Sachs has recently by invitation inspected the German Government's new fire-testing grounds at Berlin, and finds that here and elsewhere on the Continent research work in this branch is still carried on in an incomplete and primitive manner, making it difficult for any assimilation of the testing arrangements adopted in this country to those in vogue on the Continent.

Grays (Essex).—The Council have received sanction to a loan of £12,000 for electricity supply. A refuse destructor is also to be erected.

Great Yarmouth.—The Port and Haven Commission have sanctioned the application of the Corporation to lay three cables in the bed of the river near the Lower Ferry for supplying electric current in the Gorleston district. The trench for the cables is to be excavated to a depth of 21ft. below low water.

Hampstead (London).—The Vestry recently applied for a loan of £97,178 for electric lighting, but the London County Council intimated that they could only sanction the borrowing of £90,740. The Council have further intimated that as the Vestry had elected to spread the repayment of the whole of the initial cost of the installation over 42 years, the Council would decline to give its sanction to the raising of any loan to replace any of the plant and machinery which might be necessary during the currency of the loan, and would expect the Vestry to provide for all renewals required during that period out of a sinking fund or from maintenance account. The matter has been referred to the Finance committee.

The Vestry have decided to construct an artesian well, 400ft. deep, at the electricity station, capable of yielding 5,000 gallons per hour.

Infirmary Lighting.—The Fulham (London) Guardians have engaged Mr. F. H. Medhurst, at a fee of £21, to report upon the question of lighting their infirmary electrically.

Ipswich.—Prof. Kennedy's report on the electric lighting question has been received, and will shortly come before the Council for discussion.

Islington (London).—A recommendation by the Parliamentary and General Purposes committee to increase the salary of the electrical engineer (Mr. Albert Gay) from £500 to £600 per annum was considered by the Vestry at its meeting on Friday last. After a keen debate the proposal was rejected by 45 votes to 34.

Japanese Electric Railway.—It is stated by the *Electrical Review* of New York that a concession has been granted to the Tokio City Railway Co. to proceed to the construction of its proposed lines, which are to be some 200 miles in length. The capital of the company is to be 15,000,000 yen (about £1,440,000 sterling), to be spent in part as follows:—Track material, rails, &c., 3,525,000 yen; 600 electric cars, 2,140,000 yen; 6,000 H.P. power house, 1,500,000 yen; eight sub-stations, 1,000,000 yen. It is proposed to use 30 200 H.P. water-tube boilers, five 1,200 H.P. triple-expansion engines, and five three-phase, 3,500 volt, 800 kw. dynamos, direct coupled. The chief engineer of the works is Mr. Farichi Kain.

Light Railways.—The Board of Trade have, after modification, confirmed the Dudley and District Light Railways Extension Order (1900), the Mid-Suffolk Light Railway Order (1900), and the Rhyl and Prestatyn Light Railway Order (1900).

The Light Railway Commissioners propose to sanction the application of the Gloucester Tramways Co. for constructing the proposed Gloucester and District Light (Electric) Railway, subject to the Corporation waiving their right to purchase the existing tramways in the event of light railways being substituted therefor. The Corporation were recommended that, as they were expected to waive their right to purchase the existing tramways and any claim to wayleaves, and accept a right to purchase the proposed light railways within the city after 30 years, the company should be required to take electric energy at the rate of 2d. per unit for the first 200,000 units, 1¾d. per unit for the second 200,000, and 1½d. for the third 200,000; after 600,000 the price to be reduced one-tenth of a penny for every additional 50,000 units unless the price reached a minimum of 1d. per unit. The consideration of the matter has been deferred.

The adjourned inquiry of the Light Railway Commissioners into the joint application of the Middlesex County Council and the North Metropolitan Tramways Co. for permission to construct a system of light (electric) railways in Middlesex was resumed on Wednesday. Lord Jersey said they were prepared to sanction the line from

Digitized by Google

Tottenham to Wood Green, thence through Bounds Green to Southgate, from Highgate to Whetstone, and from Kilburn to Edgware Church—the three main lines and the spurs on which the generating stations were to be constructed.

An inquiry was opened on Tuesday by the Light Railway Commissioners into the application of the London County Council to construct four lines of electric tramway—viz.: (1) Clapham-common to Kingston; (2) Deptford, by Shooter's-hill, to Woolwich; (3) New Cross, by Lewisham, to Eltham; and (4) Archway Tavern, Highgate, to the county boundary. The line from Deptford to Woolwich was first considered. Mr. Cripps, Q.C., for the Council, said the line was for local convenience. It would be worked on the slotted-conduit electric system, and the Council had met the wishes of the local authorities in regard to the method of constructing the line. Sir Alexander Binnie, engineer-in-chief of the County Council, said the Council had two existing tramways, connecting New Cross and Greenwich with Westminster and Blackfriars. The proposed extension would be 5½ miles long, and would be double throughout. The route presented no difficulty in regard to gradients. It was rather steep—1 in 10—at Shooter's-hill; but heavier gradients had been successfully dealt with at Halifax and Bradford. The total estimated cost was £178,637, which included electrical equipment. The line could not be carried out without widening some of the streets, but the Council were promoting a bill by which they sought to obtain powers to carry out this improvement at an estimated cost of £37,600. Most of the local authorities favoured the scheme, the only opposition coming from some of the thinly populated districts. It was true they took powers to carry goods, but they had not laid out any goods yard. They only intended to carry what might be called tramway parcels. Dr. A. B. W. Kennedy said he had prepared the plans and sections in connection with the proposed line. At no part would there be any interference with the ordinary traffic. The external appearance of the line would be exactly like that of the Brixton cable tramway, and no part of the conductors would be exposed. The conduit system was extensively used in New York and Washington, and in many European capitals. The cost would be £3,000 per mile more than the overhead system; but in view of the anticipated traffic he thought the increased cost could be borne without financial loss. The Council sought powers to construct the generating station in the Camberwell New-road, which was a desirable site. It was proposed to use the conduit system with an insulated return, thus avoiding any chance of electrolysis. The proceedings were adjourned until yesterday (Thursday). Further evidence was given yesterday (Thursday), and Mr. Balfour Browne, Q.C., urged the Commissioners to reject the applications, as a different procedure should have been adopted and the scheme should have been submitted to Parliament. The Council were seeking, by means of a light railway order to invade the legitimate powers of local authorities. Mr. Cripps contended that the Council had adopted the right method in bringing before the Commissioners the light railway portion and going to Parliament for power to make the street improvements. The chairman said it appeared that the Commissioners were of opinion that the proposal was incomplete because only a portion of it came before them at all, the schemes would therefore be rejected. Mr. Cripps then said that if the Improvements Bill were sanctioned the objection would not apply, and consequently they proposed to appeal to the Board of Trade on this point.

Liverpool.—Mr. A. P. Trotter officially inspected the Prince's Park electric tramway route on Tuesday.

Lymington.—The Council have invited tenders from Edmundson's Electricity Corporation and the local gas and coke company for lighting the district. Both tenders will be considered at the meeting on 10th prox.

Newcastle on-Tyne.—A Board of Trade enquiry will be held on 1st prox. into the application of the Corporation to borrow £120,560 for electric tramways.

The first rail of the new electric tramway system was laid by Mrs. W. Cail, wife of the chairman of the Tramways committee, on Thursday last. The total length of the system is about 20 miles, and all the lines are double.

Nuneaton.—The Local Government Board have intimated to the Council that, in respect to the application for sanction to a loan of £16,000 for the purchase of the Nuneaton Electric Co.'s undertaking, they are not satisfied that the purchase would not involve a charge upon the rates. If the Council retain the opinion that the purchase is advisable in the interests of the district, the board will not refuse to sanction the loan, provided the Council undertook to consult an expert as to future extensions, and be guided by his advice. The board have been informed that the Council think it desirable to purchase the undertaking, and that an expert will be consulted.

Pacific Cable.—In February last the Japanese House of Representatives passed a resolution in favour of Japanese participation in any scheme for the laying of a Pacific cable.

Personal.—Mr. W. J. Furze, head of the firm of W. J. Furze and Co., electrical engineers and contractors, Nottingham, has been unanimously appointed chairman of the Basford Board of Guardians, of which body he has been a member for ten years.

Perth.—An inquiry was held on Friday into the application of the Corporation to borrow £50,000 for electric lighting and £50,000 for gas extensions. Particulars of the electric lighting scheme were given by the consulting engineer (Mr. W. C. C. Hawtayne), and to this portion of the scheme there was no objection, but Bailie Taylor and Councillor Anderson objected to the proposed expenditure on gas works.

Portsmouth.—The charge for the supply of current to public buildings has been reduced from 4½d. to 4d. per unit.

Private Bill Legislation.—The promoters of the North Metropolitan Electric Power Supply Bill have introduced a clause into this measure to empower them to compulsorily acquire lands in Enfield for the erection of an electricity generating station.

The Salford Corporation desire to introduce an additional clause in their bill before Parliament empowering them to run omnibuses in connection with any tramways owned, leased or worked by the Corporation.

The City of London Electric Lighting and the Metropolitan District Railway Bills were read a second time in the House of Commons yesterday (Thursday). The London County Council Tramways (No. 2) Bill was considered and ordered for third reading.

Provisional Order Transfer.—The Garston District Council intend to transfer their electric lighting Order to the Garston and District Electric Supply Co. (Ltd.), receiving power to purchase at 21 years, or at the end of any year thereafter. The company agree to pay the expenses of obtaining the Order and transfer.

St. James' and Pall Mall Electric Light Co. (Ltd.)—The amount of electricity sold by this company for the quarter ended March 25 is returned at 1,599,768 units (estimated to produce £28,529), as against 1,161,987 units (which produced £20,964) for the corresponding period of 1899.

Sheffield.—The Eccleshall electric tramway route has been passed by the Board of Trade.

Telephone Wayleaves.—At Southwark (London) Police Court on Monday Mr. J. A. Johnson, clerk to the Vestry of St. George the Martyr, applied for a summons against the National Telephone Co. for breaking up the roadway in Marshalsea-road, Borough, on the early morning of April 1. Mr. Johnson stated that the application was under Sec. 109 of the Metropolis Local Management Act, and was made on the strength of advice given by the judge in the case "Battersea Vestry *v.* County of London and Brush Provincial Electric Lighting Co." In that case the judge refused an application for an injunction to remove conduits which had been laid, but suggested that if a summons had been taken out under Sec. 109 of the Metropolis Local Management Act the result would have been different. In the present instance the company did not give three clear days' notice of intention to break up the road, although they had been negotiating for years for permission. The Vestry had however withheld their consent except upon certain conditions. The summons was granted.

Theft of Electrical Fittings.—At the Hull Quarter Sessions last week, before Mr. J. Forbes, Q.C., some singular evidence was given during a charge of theft. Charles Monkman, electrician; M. McElwee, labourer; and J. H. Nicholson, electrician, were indicted for stealing a quantity of electrical fittings from Messrs. Reames, Wokes and Co. The prosecutors had undertaken a contract with the Sculcoates Guardians for wiring the Beverley-road workhouse. McElwee was in their employ, and it was alleged that he purloined a quantity of fittings and sold them to the other prisoners, who fitted them into various shops in the city. Defendant Monkman gave evidence in his own behalf and said he had been in the electrical business in Hull for 16 years, and always stipulated with his employers that he should be allowed to do private work. McElwee borrowed 3s. 6d. from him, and subsequently he took to him a coil of wire and six lamp holders, and asked him to buy them. He did so, and gave him 7s. 6d. for the lot. He did not know the articles were stolen. Afterwards he sold the wire and holders to Nicholson for 10s. Nicholson said that he did private electrical work in his own time. He had no idea the things he purchased from Monkman were stolen. He paid him about two-thirds the value of them, but did not take a receipt. He knew he was getting the goods cheap. He took a ceiling rose and some holders from his employer (Mr. Hyde) without his knowledge, but had paid for them after the other two men had been taken into custody, and after Mr. Hyde had been round and seen the different shops which he (Nicholson) had fitted up. He was still in Mr. Hyde's employ, and had continued to purchase things from him. He had nearly paid Mr. Hyde for all he had taken. The Recorder said he had never heard of such a state of things in his life. Mr. Hyde said he was satisfied Nicholson was an honest, straightforward man. He took the things without his knowledge,

Digitized by Google

it was true, but he had done it before, and paid for them in the usual way. Nicholson was found not guilty, and was discharged. The other prisoners were found guilty, and McElwee was committed for one week, making 12 weeks in all, as he had been 11 weeks in custody. Monkman was sentenced to 11 weeks' imprisonment in the second division.

"The Journal."—Part No. 144 of the *Journal of the Institution of Electrical Engineers* is now ready, price 3s. 6d. Particulars of the contents are given in an advertisement elsewhere.

Workhouse Lighting.—The Preston Guardians have decided to light the Fulwood workhouse electrically.

On Monday the chairman of the Croydon Union Infirmary committee (Mr. G. J. Shirley) formally switched on the electric current in the presence of a number of visitors. The installation was erected by Messrs. W. J. Bishop and Co., to the specification of Mr. A. W. Sclater, the consulting engineer. There are about 800 lamps in the infirmary, totalling in the aggregate to 13,000 c.p.

Works Lighting.—At the recent meeting of Dr. Tibble's Vi-Cocoa (Ltd.) the chairman announced that their new extensive factory at Watford was being fitted up with a complete electric lighting plant.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers, or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

READY.

(Price 12s. 6d., by post, 13s. 3d.; Colonies, 14s.; abroad, 14s. 6d. (United States, 15s.)

"The Electrician" Electrical Trades' Directory and Handbook for 1900.—In addition to the well-known features of this Directory and Handbook (all of which have been carefully revised and brought quite up to date) a large addition has been made to the Handbook Division, including a Digest of the Law of the Telegraph and Telephone, for the use of municipalities and companies contemplating applying to the Postmaster-General for a Telephone Licence. This section of the book now includes the new model form of Licence issued by the Postmaster-General, the Telegraph Acts and Orders passed by Parliament in 1899, and other information in connection with this the latest development of electrical enterprise. The huge sheet tables of Electric Light and Power and Electric Railway and Tramway undertakings of the United Kingdom have been made quite complete. These sheets form a most complete record of electrical engineering progress in connection with electricity supply and power and traction applications. The Directory Division has been carefully extended and corrected, and is the most reliable list of firms and persons engaged in the electrical and allied industries ever compiled. A number of additional sketches of the careers of well-known electrical experts have been added to the Biographical Division, together with many new portraits. The new volume is the most complete and correct book of its kind ever published in any language.

"The Electrician" Reading Case.—To hold four numbers of the journal. Strongly bound, 1s. net; post free, 1s. 4d.

"Magnetic Induction in Iron and other Metals."—By Prof. J. A. Ewing. Price 10s. 6d. net. *New Edition (Third) now ready.*

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free. The book deals with the important subject of localising faults in electric light and power cables; and the various methods of insulation testing are here collected and discussed.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves." A Review of the Work of Hertz and his Successors.—By Dr. O. J. Lodge, with a large number of illustrations, bringing this latest application of electrical science quite up to date. New and Enlarged Edition, 5s. nett. *Now ready.*

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free. The authors give in a clear and concise manner a good summary of the general principles of electrical science.

"The Incandescent Lamp and its Manufacture."—By Gilbert S. Ram. Price 7s. 6d., post free. The principles underlying the manufacture of the incandescent lamp are carefully and fully dealt with in this volume.

"The Centenary of the Electric Current, 1799-1899."—By Dr. J. A. Fleming. Price, paper covers, 1s. net, post free 1s. 3d.; strong cloth, s. 6d., post free.

"Motive Power and Gearing for Electrical Machinery."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free. In this comprehensive work an account is given of the scientific principles and modern practice in the use of engines for dynamo driving, not only for isolated power plants, but also for public electric lighting and power stations. The various forms of gearing in the power station and for electric motors are also dealt with; and the book contains, in addition, numerous tables giving exact data of the equipment and working of electric power stations.

"The Manufacture of Carbons for all Electrical Purposes."—by Francis Jehl. 10s. 6d., post free. This is a practical handbook, giving a complete description of the art of making carbons for electric lighting, electrodes, &c., with particulars of the various gas generators and furnaces used in carbonising. The work also contains particulars of the cost, &c. of erecting and working carbon works, and plans of a model factory.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. *New and Cheaper Edition*, 6s., post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free.

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. This work gives a detailed technical summary of modern practice in manufacturing, laying, testing, and repairing submarine telegraph cables.

"Electromagnetic Theory."—By Oliver Heaviside. *Vol. I.*, 12s. 6d. *Vol. II.*, 12s. 6d.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free. The author treats fully both the theoretical principles of the art of electrolytic separation of metals and the practical rules and details of technical application on a commercial scale. The work is adapted to the use of the manufacturer as well as the student.

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d., post free. Propsectus on application. This is a complete treatise on the theory and construction of drum winding, and of commutators for closed coil-armatures, together with a *résumé* of the principal points involved in their design, and an exposition of armature reactions and sparking.

"Laboratory Notes and Forms."—We have ready a set of 40 Elementary and Advanced Exercises for use with Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of the series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnics and other Science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper, and with less space for tabulated records, are issued at half the price of the original set.

"The Alternate Current Transformer."—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. Vol. I.—*New Edition.* Price 12s. 6d., post free, Vol. II., price 12s. 6d., post free, is also ready.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"The Potentiometer and its Adjuncts": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free.

"The Students' Guide to Submarine Cable Testing."—A new edition of this book, by Messrs. H. K. C. Fisher and J. C. H. Darby, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated.

"The Steam Engine Indicator and Indicator Diagrams."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free. This work is a concise guide to the objects, construction, and use of the steam engine indicator and to the interpretation of indicator diagrams.

"The Electrician" Primers.—In Two Volumes. Vol. I., Theory Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth, 2s. 9d. Single Primers, 3d. each, post free.

"Electrical Engineering Formulæ," a pocket book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. *New Edition nearly ready.*

"Bibliography of X-Ray Literature and Research."—A valuable compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Edited by C. E. S. Phillips. Price 5s., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated, price 1s 6d.; post free, 1s. 9d. In this work the author gives useful hints as to the manufacture of electric light carbons, including the preparation of material, firing, saturating, and coring, together with a description and estimate of cost of the plant required.

"Armature Winding of Electric Machines."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s. post free.

"Temperature Coefficients of 'Conductivity' Copper." Compiled by Messrs. Clark, Forde and Taylor, consulting engineers. Strongly bound in cloth, 2s. 6d. net. Also a Sheet Table of Log. Reciprocals of Coefficients for Copper Resistances at different temperatures from 32°F. to 84·9°F. Printed on strong cardboard, 6d. net.

Digitized by Google

IN THE PRESS.

"The Electric Arc."—By Mrs. Ayrton.

"Secondary Batteries, their Design and Manufacture."—By E. J. Wade.

"Primary Batteries: Their Construction and Use."—By W. R. Cooper.

"Practical Telephony."—By Dane Sinclair and F. C. Raphael.

"'The Electrician' Wireman's Pocket-book."—Edited by F. C. Raphael. *Nearly ready.*

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

The *Heywood* Corporation require tenders for the supply and erection of electricity generating plant, particulars of which are set out in an advertisement. Copies of specification, &c, may be obtained from the offices of the town clerk (Mr. J. H. Baldwick) after 30th inst.; and specifications and plans may also be obtained from the consulting engineer (Mr. W. P. Adams), 35, Queen Victoria-street, London, E.C., from whom further information can be obtained. Tenders addressed to the town clerk, Municipal Buildings, Heywood, Lancs., must be delivered before noon on May 14.

The Commissioners of the Royal Burgh of *Perth* invite tenders for the supply and erection of 45 enclosed arc lamps and ornamental cast-iron and steel pillars, with switch gear, &c. An advertisement contains additional particulars, and specifications may be obtained at the offices of the clerk (Mr. John Begg), City Chambers, Perth. Plans can be seen and further information obtained at the offices of the consulting engineer (Mr. W. C. C. Hawtayne), 9, Queen-street-place, London, E.C., and Central Chambers, 93, Hope-street, Glasgow. Tenders must be delivered before noon on May 7.

The *Salford* Electric Light committee require tenders for two miles of low tension single cable, lead covered, and a battery of accumulators. An advertisement contains further particulars, and specifications, &c., may be obtained from the electrical engineer (Mr. Chas. L. Turner), Walness-road, Broughton. Tenders (addressed chairman of committee) must be delivered at the offices of the town clerk (Mr. L. C. Evans), Town Hall, Salford, before 10 a.m. of May 7.

The Streets committee of the Corporation of *London* invite tenders for the supply on hire of electrically-driven dust carts. An advertisement contains further particulars, and tenders must be sent to the town clerk (Sir John B. Monckton), Public Health Department, Guildhall, E.C., by June 1.

The *Manchester* Tramways committee invite tenders for 150 car trucks, tramway bonds and special track work and points and crossings. Specifications may be obtained from the general manager (Mr. J. M. McElroy), Tramway Department, Town Hall, Manchester, and tenders (addressed Chairman of committee) must be in by May 7. An advertisement gives further particulars.

The *Paddington* (London) Vestry invite tenders for carrying out certain work in connection with proposed alteration to the existing electric lighting at the public baths. Copies of specification can be obtained from the surveyor (Mr. George Weston), and tenders must be delivered to the vestry clerk (Mr. Frank Dethridge), Vestry Hall, Harrow-road, London, W., by noon of May 14. An advertisement gives further particulars.

The Guardians of the *West Ham* Union invite tenders for the erection of works detailed in an advertisement elsewhere. It will be seen that the tenders are to include maintenance of the installation for 12 months from the date of completion of the whole of the works. The advertisement contains further important particulars of the conditions, and tenders have to be sent in to Mr. Fred. E. Hilleary, clerk to the Guardians, Union-road, Leytonstone, E., by Wednesday, May 16.

The *Burnley* Corporation invite tenders for laying about 2,000yds. of cable. Tenders to Mr. A. Steele Sheldon, town clerk, by May 14. See advertisement.

The *King's Lynn* Corporation invite tenders for the supply of steam dynamos, boiler, switchboard and cables. Tenders by May 17.

The *Birkenhead* Corporation invite tenders for steam pipe work, &c. Tenders by May 15.

The *Wimbledon* District Council require tenders for erecting additions to the electricity station building. Tenders to clerk by May 15.

The *Keighley* Corporation require tenders for steel roofs and girders for the electricity works. Tenders by May 1 to electrical engineer.

The *Central Electric Supply Co. (Ltd.)* invite tenders for the supply, delivery and erection of electricity generating plant. Specifications from general manager (Mr. F. J. Walker), 19, Carnaby-street, Golden-square, London, W., to whom tenders by 10 a.m. of May 22.

The *Rhyl* District Council invite tenders for the supply and erection of electricity generating plant. Tenders to Clerk by 2 p.m. of May 14.

The *Great Eastern Railway Co.* require tenders for stores, including telegraph materials, bolts, screws, tools, &c. Tenders to secretary (Mr. W. H. Peppercorne) by 10 a.m. on May 8.

The *Glasgow* Corporation require tenders for opening trenches and supplying and laying underground conduits for telephone purposes, &c. Tenders to town clerk (Sir J. D. Marwick) by 30th inst.

The *Glasgow* Corporation also invite tenders for electricity meters. Tenders to Town Clerk before May 5.

The *Plymouth* Corporation invite tenders for overhead line construction, &c. Tenders to borough electrical engineer (Mr. John H. Rider) by May 2.

The *Southampton* Corporation invite tenders for a 300 kw. continuous-current generator. Tenders to Town Clerk by May 1.

The *Brighton* Corporation invite tenders for the supply of incandescent lamps for 12 months from July 1 next. Tenders to Town Clerk by June 11.

Tenders are invited until May 3 by the *Bienrerida* Municipal Council (Badajoz), Spain, for the concession for electric lighting for two years. Tenders to el Secretario del Ayuntmiento.

The *Swedish* Government invite tenders until May 3 for the supply of telephone cables, as follows:—2,000 metres (204 wires) underground cable; 10,000 metres (28 wire) overhead cable; 10,000 metres (14 wire) overhead cable.

The *Aarhus* (Denmark) Council invite tenders for delivering and laying down network for distribution of electricity. Tenders by 20th inst., to Aarhus Gas Works.

TENDERS RECEIVED AND ACCEPTED.

A short time back tenders were invited privately for wiring and installation work at King's College, London, and five tenders were submitted. It will be seen from the list below that a higher tender than the lowest has been accepted, and one of the tendering firms, whose offer was much below that of the accepted tender, complains that its offer was rejected. As, however, the specification contained the usual clause that the Council of King's College did not bind themselves to accept the lowest or any tender, there can be little real cause for complaint. We understand that the committee of King's College who considered the tenders were unable to come to a decision at a first meeting, and consequently held a second to discuss the whole question in consultation with their engineer. The dissatisfaction expressed over this contract points to the unwisdom of seeking tenders by other means than public advertisement:—

	Iron tubing.	Wood casing.
Tamplin and Makovski (*accepted*)	£1,656 0 6	£1,444 5 9
Alliance Electrical Co.	1,722 0 0	1,644 10 0
Drake and Gorham	1,343 0 0	1,209 15 0
National Electric Wiring Co.	£1,173 8 4	
J. O. Grant	1,160 0 0	

The Keighley Corporation have accepted the tender of Messrs. G. H. Woods and Co. for wiring the new municipal offices at £220.

The tender of the National Electric Wiring Co. has been accepted for wiring the Gloucester Library and municipal schools at £372. 13s.

The Bedford Corporation have accepted the tender of Messrs. W. Courte and Son for the supply and erection of two Lancashire boilers at £1,322. Eight tenders varying in amount from that accepted to £1,750 were submitted.

APPOINTMENTS VACANT AND FILLED.

A chief assistant to the superintendent engineer is required for the Bradford Corporation electricity department. An advertisement contains further particulars, and applications to the city electrical engineer (Mr. R. A. Chattock), Town Hall, Bradford, must be in by May 2.

The States of Guernsey require a local manager for their telephone exchange. Applications to Mr. A. R. Bennett, City Chambers, Glasgow. An advertisement contains additional particulars.

A chief assistant is required for an alternating current electricity station. See advertisement.

A shift engineer is required for the Taunton electricity works. Applications to the Borough electrical engineer (Mr. Ed. B. Thornhill) by May 5. See advertisement.

A junior assistant engineer is required by the Dover Electricity Supply Co. (Ltd.). See advertisement.

Thirty-one tenders have been received for the electric lighting of the Northumberland County Lunatic Asylum, and the report of Mr. A. A. Campbell Swinton upon these tenders is to be considered at the meeting of the Visiting Committee on 21st May.

Digitized by Google

The Brighton Corporation require a resident electrical engineer to act under the consulting engineer (Mr. Arthur Wright). Applications town clerk (Mr. F. J. Tillstone) by 10 a.m. of 30th inst.

A chief clerk and book-keeper is required for the Shoreditch electric lighting department. Applications to vestry clerk by May 9.

The Manchester Tramways committee require a foreman platelayer, a foreman pavior, and a yard foreman. Applications (addressed to chairman of committee) to Town Clerk by 30th inst.

A second assistant engineer is required at the York electricity works. Applications to the city electrical engineer (Mr. C. A. Midgley) by May 7.

BANKRUPTCIES, LIQUIDATIONS, &c.

The discharge of E. L. Joseph, electrical engineer, 109, Brondesbury Villas, Brondesbury, and Northampton Works, Northampton-grove, Canonbury, London, is suspended for three years because, (1) the assets are not equal to 10s. in the £, and (2) debtor had contracted debts without reasonable expectation of being able to pay them, and had incurred unjustifiable expense by bringing a frivolous or vexatious action.

In the bankruptcy of Edwin Bates, electrician (now or lately trading at 4, Hopwood-avenue, Manchester, with W. H. Walley, as E. Bates and Co.), the first meeting of creditors will take place on May 2 at the O.R.'s, Byrom-street, Manchester, and the public examination on May 28 at the Court House, Manchester.

The Perfect Arc Lamp and Accessories Co. (Ltd.) is to be wound up voluntarily, and Mr. S. H. Lee, 185, Gracechurch-street, E.C., is liquidator.

Claims against Cuttriss, Wallis and Co. (Ltd.) must be sent by June 6 to the liquidator, Mr. J. W. Close, Greek-street Chambers, Leeds.

Plant for Sale.—The National Telephone Co., Royal Exchange, Glasgow, have for sale a motor generator by Mavor and Coulson and a Crocker-Wheeler motor. See advertisement.

A complete private electric lighting plant is advertised for sale in another column. Applications to Mr. Thomas J. Barratt, Bell Moor House, Upper Heath, Hampstead, London, N.W.

Telegraph Stores for Sale.—Tenders are invited for the purchase of old telegraph stores, particulars of which are set out in an advertisement. Forms of tender can be obtained from the controller of stores (Mr. Chas. E. Stuart), G. P. O. West, London, E.C, and tenders must be in by 10 a.m., May 9.

Parsons Steam Turbine.—Messrs. Brown, Boveri and Co. and the Parsons Foreign Patents Co. have entered into an agreement for the manufacture and sale, for electrical purposes, of the well-known Parsons steam turbine in France, Germany, Russia, Switzerland and Italy, and a company styled the Aktien-Gesellschaft für Dampf-Turbinen (System Brown-Boveri-Parsons), has been registered in Switzerland, with head office at Baden, for the purpose of carrying on the business. The combination is an important one in view of the position Messrs. Brown, Boveri and Co. hold on the Continent as manufacturers of electric generating plant.

Electrical Inkless Printing.—Some time back we received a circular from the Electrical Inkless Printing Syndicate (Limited), in which reference was made to a pamphlet on "Picturesque Dovercourt," stated to have been recently issued by the syndicate as an example of the printing work produced by the syndicate's machinery and patented method of production. In the printing trade it is pretty generally thought that the sensitiveness of the chemically-prepared paper used in the syndicate's process becomes exhausted when one side of the paper has been printed upon. This, however, the syndicate denies, and claims that paper has been printed on one side only and laid by for a lengthened period, and when again put through the machine for printing on the reverse side has at once responded to the electric current. These statements and claims are interesting not only to the printer but to the electrician, and it would be distinctly in the syndicate's interest from every point of view to clearly and publicly demonstrate their truth or falsehood. The syndicate does not readily respond to the efforts made by the technical press to obtain particulars of its process.

French Patents and the Paris Exhibition.—Messrs. J. C. Chapman and Co., 70, Chancery-lane, W.C., write to point out that in connection with the International Exhibition at Paris this year, a short law was enacted in December, 1899, by which "any person who shall have exhibited at the Universal Exhibition of 1900 an article similar to that covered by his patent, shall be considered, so far as is necessary, as having worked his discovery or invention in France during the course of the Exhibition." The French law provides two years' delay for working any patented invention, and by default of such working forfeiture is incurred, but by the above law, patented inventions exhibited and "worked" during the exhibition, the period of delay will recommence either from the date of the official closing of the exhibition, or from the date of an earlier order by the authorities for removal of the article. The exhibition of a patented article therefore constitutes sufficient compliance with the working provisions of the French Patent Law. It is advisable for those who exhibit patented articles to obtain a sufficient certificate or proof thereof, as in the case of ordinary working, for subsequent use should the validity of their patents be attacked.

Accumulator Plates.—An advertisement on p. 22 announces that Mr. O. R. Schulz, patent agent, 171, Leipzigerstrasse, Berlin, W., is prepared to grant manufacturing licences for what is claimed to be a good and rapid process for producing electrodes of any kind with large surfaces, without injurious chemical constituents. Or the process may be purchased outright.

"Buffoline" Noiseless Gearing.—The Buffoline Noiseless Gear Co., of Chapel-street, Levenshulme, near Manchester, forward particulars of special types of gearing manufactured by the company on spur, bevel, single or double helical, with machine cut teeth, for motors, pumps, cranes, motor cars, and for general machinery. These wheels are claimed to have been tested to be more than twice the strength of cast iron. The company undertake to cut spur wheels up to 11ft. diameter.

Interior Conduit Systems.—Messrs. Pryke and Palmer have issued an illustrated list of interior conduit fittings. This firm claims that its system was placed before the trade some years ago and was the original conduit wiring system.

British Westinghouse Plant.—Circular No. 1,026, issued by the British Westinghouse Co., is entitled "Compensators for A.C. Circuits," and illustrates and describes Westinghouse compensators of the E and F types.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from April 13 to April 24, with the ports of destination:—

Africa—Alexandria, £24; Cape Town, £71; Chinde, £866 (including £854 telegraph material); Durban, £979 (including £832 telegraph material); East London, £75; Port Elizabeth, £164. *Argentina*—Buenos Ayres, £331 (including £244 telegraph material). *Australasia*—Adelaide, £14; Auckland, £101; Canterbury, £11; Christchurch, £28; Freemantle £42 (including £17 telegraph material); Launceston, £200; Melbourne, £271 (including £50 telegraph material); Port Chalmers, £58; Sydney, £1,180; Townsville, £763; Wellington, £706. *Belgium*—Brussels, £34; Ostend, £105. *Ceylon*—Colombo, £295. *Channel Islands*, £115. *China*—Shanghai, £310; Tientain, £76 (telegraph material). *Denmark*—Copenhagen, £121 (telegraph material). *France*—Havre, £100. *Germany*—Hamburg, £985 (including £900 telegraph material); Stettin, £60. *Gibraltar*, £11 (telegraph material). *Holland*—Amsterdam, £135; Flushing, £78; Rotterdam, £100 (telegraph material). *Hong Kong*, £510. *India*—Bombay, £476 (including £83 telegraph material); Calcutta, £2,742 (including £655 telegraph material); Madras, £131. *Malta*, £140. *Mauritius*, £75. *Peru*—Callao, £15,000 (telegraph cable). *Russia*—Odessa, £80 (telegraph material). *St. Vincent*, £163,000 (telegraph cable). *Straits Settlements*—Singapore, £434 (telegraph material). Total (for 12 days) £191,047, against £35,575 for one week last year (April 19 to 25).

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by Messrs. J. C. Chapman and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

March 24, 1900.

5,561. R. Rougé and G. Faget. London. Transformer of alternating currents into continuous currents of equal or different tension. (Date applied for under Patents, &c., Act, 1883, sec. 103, Sept. 27, 1899, being date of application in France.)

5,562. R. Rougé and G. Faget. London. Improvements in apparatus for transforming single and multiphase alternating currents into continuous currents and inversely. (Date applied for under Patents, &c., Act, 1883, sec. 103, Nov. 14, 1899, being date of application in France.)

5,567. E. Andreas. London. Improvements in or relating to plug contacts.

5,569. W. P. Thompson. Liverpool. Improvements in or connected with electric storage batteries. (E. A. Sperry, United States.)*

5,585. R. Arno. London. Improvements relating to the measurement of electric power and energy in three-phase alternating-current systems. (Date applied for under Patents, &c., Act, 1883, sec. 103, Aug. 26, 1899, being date of application in Italy.)

5,593. A. Wright and The Reason Manufacturing Co. (Ltd.) London. Improvements in electricity meters.

6,028. E. W. Mix. London. Improvements in brush-holders for dynamo-electric machines.*
6,054. H. C. Jobson. London. Improvements in telegraph poles.
6,069. R. Lundell. London. Improvements relating to the generation of direct electrical currents and to apparatus therefor.*

April 2, 1900.

6,101. H. Oppenheimer. London. Improvements in and connected with microtelephones. (Actiengesellschaft, Mix, and Genest, Germany.)
6,103. R. O'Brien. Manchester. Improvements in and relating to shade rings for use in connection with electrical and other lamp-holders.
6,129. R. von Grätzel. London. Improvements in and connected with the production of paste carriers for collectors of electricity.
6,138. A. F. Spooner. London. Improvements in and relating to synchronous motors, more especially applicable to combined cinematographic and phonographic apparatus. (H. Joly, France.)
6,141. A. F. Evans. London. Improvements in magneto-electric generators for electric ignition purposes.
6,153. P. M. Justice. London. Improvements in and connected with electrically propelled motor vehicles. (Columbia and Electric Vehicle Co., United States.)*

April 3, 1900.

6,165. J. Swinurne. London. Improvements in incandescent lamps.
6,188. J. B. Boutillier and W. B. Hunter. Glasgow. Improvements in armoured conduits for electric wires.*
6,204. H. C. Longsdon and S. Dale. Keighley. Improvements in and appertaining to switches for electro-motors.
6,209. G. Brewer. London. Improvements in electric bonds for street-mains. (A. A. Knudson, United States.)
6,217. P. H. Rosenbach. London. An improved compound or material for bearings, valves, cells for storage batteries and similar purposes.*
6,218. C. L. Coffin. London. Improvements in machines for electrically heating, welding, or working metals.*
6,237. J. Schwarzenbach. London. Improved electrical gas igniting apparatus.
6,244. L. David. London. Improvements in and apparatus for manufacturing plates for secondary electric batteries.
6,261. C. W. Atkinson. London. Improvements in electric switches and resistances.*

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

5,100. Cooper and Ridley. Methods for charging and discharging accumulators.
5,104. Braun. Reinforcement of electrical waves and avoidance of loss by straying reflection and the like by means of a condenser.
5,211. Miller. Electric incandescent lamps.
5,468. Wise (Thowless). Incandescent bodies for electric incandescent lamps.
5,543. Cohen and Cole. Multiplex selective systems of wireless telegraphy.
5,734. Vitali. Hydrocarbon engines for driving dynamo-electric machines and dynamo-electric machines driven thereby.
5,797. Rhodes. Alternating-current induction motors.
6,032. Loubery, Francois and Kunkelmann. Electricity registers or meters.
6,054. Berditschewsky-Apostoloff. Electric lamps.
6,690. Lamme. Method of and means for varying the speed of direct current motors. (Date applied for under International Convention, Sept. 3, 1898.)
6,691. Lamme. Systems of electrical distribution and regulation. (Date applied for under International Convention September, 28, 1898.)
6,712. G. Aboilard et Cie. Lines, circuits and apparatus for telephonic intercommunication. (Date applied for under International Convention, August 30, 1898.)
6,873. Prestwich. Accumulators or secondary batteries.
6,947. Wydts and Weissmann. Method of and apparatus for transforming continuous electric currents into continuous or alternating currents of different voltage.
7,415. Cary and Delevy. Electrical cooking apparatus.
7,594. Bowley. Phonographs and the like.
7,856. Royal. Coin-freed gramophones or the like.
7,641. Cole and Cohen. Hertzian wave telegraphy to enable signals to be transmitted to any distance by means of intermediate relay stations.
8,340. Berry and Wallis-Jones. Electric welding or metal working apparatus.
8,522. Welford. Storage batteries.
8,949. Belfield (Perkins). Starting mechanism for electric motors.
8,957. Reason and Mutual Electric Trust (Ltd.) Connecting devices for electric conductors.
8,961. Poulsen. Method of and apparatus for effecting the storing up of speech or signals by magnetically influencing magnetisable bodies.
9,101. Pennycuick and Barrett. Globes or protectors for electric and other lighting apparatus.
9,278. Statter. Dynamo electric or electrodynamic machines.
9,351. Strecker. Manufacture and production of elements for secondary batteries or electric accumulators.
9,414. Leitner. Controlling electric motors and apparatus for that purpose.
9,456. Niblatt and Sutherland. Electric storage or secondary batteries.
9,512. Abel (Soc. d'Etude des Piles Electriques). Voltaic batteries.
8,518. Veyey. Automatic telephonic switches.
9,523. Lamme. Distribution of electric currents. (Date applied for under International Convention, Oct. 6, 1898.)
9,690. Denayrouze. Incandescence lamps. (Date applied for under International Convention, October 19, 1898.)
9,966. Boult (Jungbluth). Manufacture of protecting casings or tubular structures for electric cables.
10,163. Lake (Scott). Electric circuit breakers.
10,228. Boult (von Zweigbergk). Electric controllers.
11,424. Marino. Accumulator batteries.
11,552. Voigt and Haeffner. Electric tumbler switch.
11,880. Croneau. Portable electric drilling machine.
13,733. Abel (Soc. Anon. pour la transmission de la Force par l'Electricité). Apparatus for exciting alternating current dynamos.
15,019. Gillmore. Telephone switches and switchboards.
16,494. Groome. Automatic cut-off devices principally designed for controlling the flow of fluids and of electric currents.
16,650. Petersen. Conduits suitable for electric mains.
18,350. Marino. Electrolytes.
20,328. Robison. Dynamo electric generators or transformers.
21,378. Halsey. Combined maximum and integrating electric meter. (Date applied for under International Convention, March 27, 1899.)
21,777. Szanka and Ganz and Co. Eisengiesserei und Maschinen-Fabriks Actien-Gesellschaft. Electric condurting sheaths or coverings for articles of ceramic or pulverulent materials.
22,081. Schiff. Micro telephones.

23,219. BOULT (Cumont). Electric signal alarm and safety devices for railways.
23,540. HART. Graphophone reproducers.
24,614. RIES. Telephone systems and apparatus.
24,673. BUTCHER. Electric clocks.
24,739. ELY. Electric switches.
25,491. MARINO. Accumulator batteries.

1900.

547. PAYNE. Process of and apparatus for magnetic separation.
1,276. BOULT. (Soc. E. Giraud et Cie.) Electric chain-link welding machines.
1,309. EARLE. Manufacture of compound metal tubes suitable for gas and electrical conductors.
2,077. CHEVAL and LINDEMAN. Accumulator battery.
2,271. BOULT. (Soc. Anon. des Moteurs et Voitures "Aigle.") Electric ignition devices for explosion engines.
2,357. SIEMENS BROS. AND CO. (LTD.) (Siemens and Halske Aktien Gesellschaft.) Electro-magnetic bell signalling apparatus.

COMPANIES' MEETINGS AND REPORTS.

Eastern Extension, Australasia and China Telegraph Co. (Ltd.).

The fifty-third half-yearly general meeting of this Company was held on Wednesday at Winchester House, London, under the presidency of the MARQUIS OF TWEEDDALE, K.T.

The MANAGER and SECRETARY (Mr. F. E. Hesse) read the notice convening the meeting, and the minutes of the previous meeting, which were duly confirmed and signed by the Chairman, after which

The CHAIRMAN said: Gentlemen, I think that you will consider the report and accounts satisfactory. (Hear, hear.) The gross revenue for the half-year under review has amounted to £339,450, against £290,431 for the correeponding period of 1893, showing an increase of £49,019. About one-half of this increase is derived from Australasian traffic, the remainder being spread over the rest of the system, but more particularly the Manila, Japan, and China sections. The working and other expenses have amounted to £116,935, against £100,085 for the corresponding period of 1898, showing an increase of £16,850, which, as will be seen from the printed accounts, is almost entirely due to the "Expenses attending the maintenance of cables" being considerably heavier than in 1898. The balance of increase is attributable to the special payments made to the Philippines staff to recoup losses, &c., during the insurrection and war in those islands, and also, to a smaller extent, to expenses connected with negotiations with foreign and other Governments. Comparing the figures for the whole year, the results are as follows: Gross receipts, £663,811, against £567,713 for the year 1898, or an increase of £96,098, while the expenses for the past year amounted to £224,201, against £202,958 for the year 1898, showing an increase of £21,243, accounted for as already explained. The usual interim dividends have been distributed during the past year, making with the final dividend proposed to be paid to-morrow a total payment of 5 per cent. for 1899. A bonus of 4s. per share, or 2 per cent. will also be paid, making a total distribution for the year of 7 per cent. The revenue balance of £86,582 has been carried to the general reserve fund, which now stands at £967,581, after having charged against the fund £58,901 for cable renewals, &c., carried out during the June half of 1899. It will also be observed from the printed report and accounts that the subsidy of £32,400 per annum, payable by certain of the Australasian Governments in respect of the duplicate cable between Penang and Australia, ceased on Oct. 31 last. The original debenture debt amounted to £640,000, which will be entirely extinguished when the 333 debentures now outstanding are paid off on July 2 next. The Tariff Guarantee Agreements entered into several years ago with the Australasian Governments will also come to an end during the next few days; but, on the other hand, a new agreement has recently been concluded with the Governments of South Australia, Western Australia, and Tasmania for immediately reducing the tariffs between the contracting Colonies and Europe (varying between 4s. 9d. and 5s. 1d. per word) to an uniform rate of 4s. per word, with proportionate reductions for Government and press telegrams. Should the "standard revenue" fixed by the agreement be maintained, a further reduction—to 3s. 6d. per word—will take place on January 1 next, to 3s. on January 1, 1902, and to 2s. 6d. on January 1, 1903. The agreement, moreover, provides for the extension by this Company, in conjunction with the Eastern Telegraph Co., of the third cable recently laid by the latter company to South Africa—by laying a direct cable from Durban to Perth and Adelaide, via Mauritius, Rodriguez and Cocos Islands; and when this cable is opened for traffic, the tariff between the Contracting Colonies and South Africa will be reduced from 7s. 1d. per word to about 2s. 6d. The Company have not asked for any subsidy or guarantee in return for the reduced rates and improved communication which the new cable will secure, but only for the right to have their own land wires and offices in the capitals of the contracting Colonies when the proposed Government Pacific, or other competing cable is laid. At present the Company's cables are landed more than 2,000 miles away from the principal capitals in Australia, and the traffic is consequently dependent on the good working of the long Government landlines across the Australian Continent—which landlines might not be so efficiently maintained as they are at present when the Governments owning them are federated, and in competition with the Company for the international traffic. (Hear, hear.) On the other hand, the new cable will terminate in the heart of Australia, and with the right to deal direct with the public and transmit their own traffic from end to end, the Company will be placed on terms of equality with their opponents; and on that basis they do not fear the result should competition arise. (Cheers.) Strange to say, grave concern has been evinced in Canada, New Zealand, Queensland and elsewhere at the prospect of the Company enjoying in Australia the right so readily accorded in this country and in Canada itself, both to foreign and British cable companies, of direct dealings with the public; and not only have the Company's motives and intentions been misinterpreted in those Colonies, but strong protests have been made by the Governments of Canada, New Zealand, and Queensland against the Australasian Governments granting any such privilege to the Company. Nevertheless, as I have already mentioned, three of the Australasian Governments have agreed to grant the privilege; and the Governments of New South Wales and Victoria having accepted the agreement in principle, are expected to join in the arrangement very shortly. (Applause.) The protest to which I have alluded is based on the ground that if the privilege is granted it will make the Government Pacific Cable a financial failure; but the real objection appears to be that the prospects of the Company will, in all probability, and at no very distant date, lead to a reduction of the tariff to 2s. 6d. per word; an objection, however, scarcely consistent with the ostensible objects of the Pacific scheme—namely, the breaking up of the Company's so-called monopoly and the cheapening of the cable rates to Australasia. It would almost seem that the promoters of the Pacific cable are not averse to creating a Government monopoly and the consequent discouragement of all private enterprise, if by those means a tariff can be maintained sufficiently high to make the Government Pacific cable a paying concern. However that may be, the danger has been averted by the action of the three Australasian Governments with whom we have concluded our agreement—an agreement which I believe will be approved by everyone present. (Hear, hear.) We have a fair field now before us, and no favour; and we have no doubt we shall be able to hold our own against all comers from whatever quarter proceeding. (Cheers). You will have learned from the report that it is proposed to add to the Directorate by electing Sir John Wolfe Barry, K.C.B., to a seat at the Board; and accordingly to increase the remuneration of the Directors to £4,500 per annum. Although the Directors have power, as you are aware, to fill up casual vacancies in the directorate, yet—having regard to the intimation given to the shareholders when the last vacancy occurred, that it was not then proposed to fill it up—your Directors desire to have the concurrence of the shareholders in the election of an additional Director. Moreover, it has been thought undesirable that the number of Directors should remain at the minimum fixed by the Articles of Association, as in case of a casual vacancy occurring, it might lead to some inconvenience, notwithstanding the resolution passed at a recent general meeting giving the Directors power to carry on the business of the Company during the casual vacancy. Sir John Wolfe Barry is, as you are doubtless aware, a Director of the Eastern Telegraph Co., and your Directors have much pleasure in proposing his election as a Director of this Company. He is well known as an engineer of the highest eminence, and the Company, I think, may be deemed very fortunate in securing his services as a Director. With these observations, I beg to propose—

"*That the Report and Accounts of the Directors now submitted be received and adopted, and that a dividend be now declared of 2s. 6d. per share together with a bonus of 4s. per share, both free of income tax, payable on the 26th inst., making with the previous distributions a total payment of 7 per cent. for the year 1899.*"

Mr. FRANCIS A. BEVAN seconded the resolution.

The CHAIRMAN invited discussion, but no one rising to address the meeting, he put the resolution, and it was carried unanimously.

Mr. BEVAN afterwards proposed the re-election as a Director of the Marquis of Tweeddale, remarking that no words of his were required to put the resolution before the shareholders in the most favourable manner.

Mr. JOHN DENISON-PENDER seconded the motion, which was carried unanimously.

The CHAIRMAN: I beg to thank you very warmly, gentlemen, for your renewed confidence. Continuing, the Chairman proposed the re-election as a Director of Mr. Bevan.

The Hon. GEORGE PEEL seconded the motion, which was carried unanimously.

The CHAIRMAN then proposed the election as a Director of Sir John Wolfe Barry, K.C.B.

Sir ALBERT J. LEPPOC CAPPEL, K.C.I.E., seconded the resolution, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. CLEMENT S. COLVIN, C.S.I., the following resolution was afterwards carried unanimously:—

"*That the minimum annual renumeration of the Directors be increased from £4,000 to £4,500, such sum to be divided between the Directors as they may from time to time determine.*"

The retiring auditors, Messrs. Deloitte, Dever, Griffiths and Co. and Messrs. Welton, Jones and Co., were afterwards re-elected.

Mr. JOHN NEWTON then proposed a vote of thanks to the Chairman and Directors for their services. He remarked that the past year had not been an ordinary one for the holders of telegraph stocks. Many rumours had been going about, and they were accused of being the most gigantic and pernicious monopoly ever known in the world. This was because they were paying a dividend of 7 per cent., but those who knew what the enterprise was at the outset would not consider 7 per cent. an extraordinary return even in these days. The Directors had struggled in the most successful manner, and had achieved an excellent position for the Company. (Applause.)

Mr. W. T. ANSELL seconded the resolution, which was carried unanimously.

Digitized by Google

The CHAIRMAN: I beg to thank you, on the part of my colleagues and myself, for the handsome way in which this motion has been proposed and seconded and received by you. I think it is two years ago since I said with respect to the Pacific cable that we should successfully look after your interests, and I think that we have done so. (Cheers.)

The proceedings then terminated.

Dudley, Stourbridge, and District Electric Traction Co. (Ltd.).

The eighteenth ordinary general meeting was held on Tuesday, Mr. EMILE GARCKE presiding.

The SECRETARY (Mr. H. S. Hodgson) having read the notice calling the meeting,

The CHAIRMAN (in moving the adoption of the report and accounts) said: Gentlemen, this is practically the first meeting that has been held since the conversion of the line from steam working to electric traction. As as 1880, and the undertaking has for many years been worked by steam power. Some few years ago the British Electric Traction Co. acquired the majority of the shares of the company with a view to introducing electric traction. They commenced negotiations with the various local authorities, which proved rather a slow process. Nevertheless, arrangements satisfactory to all parties were made, with the result that the tenure was so extended as to permit of the expenditure of the additional capital requisite for reconstructing the permanent way, erecting power houses, providing new cars, and electrical equipment generally. Under the Tramways Act, of course, the local authorities were entitled to purchase the tramways on the expiration of a period of 21 years from the date of the order, which would be in 1902, and obviously the period remaining was too short to justify the large outlay which electric traction made necessary; and it therefore became absolutely incumbent on the Directors to make the fresh agreements with the local authorities to which I have referred. These agreements are not the same throughout the district. They vary according to circumstances, but, speaking generally, we have an extension of life for our lines ranging from 21 to 35 years, according to the different sections. In addition to making these agreements which have enabled us to convert the old lines from steam to electric traction, we have obtained powers for extensions in the district which we believe will very materially improve the results of working on the main line from Dudley to Stourbridge. These extensions have been promoted under the Light Railways Act, and the powers obtained under two separate orders. The first of these orders was confirmed by the Board of Trade in 1898, and the lines authorised by that order have been in course of construction for some little time, and I am glad to say that they are now nearing completion. We shall lose no time with the construction and equipment of these light railway extensions, and when they have been completed we shall have upwards of 16½ miles worked electrically by this company, as compared with the original line of about 5½ miles which the company was working by steam before the British Electric Traction Co. obtained control of the undertaking. It is obvious, therefore, that the whole aspect of the company's undertaking will have undergone a considerable change by the time these new lines are completed. The capital necessary for the electrical conversion of the line has so far been provided by the British Electric Traction Co. A few years ago the tramways of the Dudley and Stourbridge Co., 5½ miles long, were isolated from the other tramways in the district, yet by means of the various powers which the British Electric Traction Co. has obtained, these tramways now form part of a very important network of tramways and light railways traversing the whole of South Staffordshire and parts of the adjoining counties. A very important undertaking has been authorised under the Kinver Light Railways Order. That will join the Dudley-Stourbridge lines at two points, and will bring that very popular holiday resort into direct communication not only with Stourbridge, Brierley Hill, and Dudley, which are served by this company's lines, but also with other and more distant centres of population in what is known as the Black Country. Then, by means of one of the Light Railway Orders I have referred to, this company's lines have been connected with the tramways of the Dudley and Wolverhampton Co, which formerly were independent and completely isolated, being separated from the other tramways in South Staffordshire in the same way as the tramways of this company were. Then the fact that the British Electric Traction Co. have very large interests in the South Staffordshire Tramways Co., and have recently acquired the controlling interest in the Birmingham and Midland tramways, will make it possible, we hope, to arrange for mutual running powers over the other lines, in a way which will enable passengers on any part of this company's system to reach any other tramways in the very large and important district of South Staffordshire. Instead, therefore, of being a comparatively short line of 5½ miles, this company's system will form in a measure the centre of a very much larger system, and the traffic is almost certain to be very much greater per mile than it has been in the past. The existing tramways were opened for electric traction in July last year, and since then a very satisfactory service of electric cars has been provided over that route, but in view of the fact that the whole of our organisation—the character of the cars, the power-house, the car depôts—has been made with a view of providing for a larger service than is being run on the 5½ miles, it is difficult, if not impossible, to accurately gauge the results of the past few months' working as affording any indication of what will be the conditions of working in the future, when the other lines authorised by the Light Railways Orders have been completed. Nevertheless, it will be of interest to shareholders that I should state that, not only the number of passengers carried, but also the receipts, have increased by more than 50 per cent. as compared with the time when the lines were worked by steam. We propose to work, on behalf of the British Electric Traction Company, the Kinver Light Railways as soon as they are completed. With regard to the appropriation of the balance to the credit of profit and loss account, the amount is £4,309, exclusive of the sum brought forward from the previous year, and the Directors propose, after paying the preference dividend, that a dividend should be paid on the ordinary shares at the rate of 3 per cent. per annum for the past year, that £1,000 should be placed to depreciation fund, and that the relatively large balance of £2,313 should be carried forward. It would have been possible to pay a very much larger dividend than is proposed, but in view of the fact that a large amount is owing to the British Electric Traction Co. for construction works, which at present does not figure in the capital account, the directors deemed it more prudent that the dividend on this occasion should be at no higher rate than that which has been paid during the last few years, and that as large a balance as possible should be carried forward until the capital account had been adjusted in a way which would provide for the liabilities of the company, and until the other lines had been opened and had been working some time it was not advisable, in the opinion of the board, that the dividend should be largely increased. I conclude by moving the resolution.

The resolution was carried unanimously. The retiring directors and auditors were re-elected, and the proceedings terminated.

Kidderminster and District Electric Lighting and Traction Co. (Ltd.)

The second ordinary general meeting of this Company was held on Wednesday, Mr. J. S. RAWORTH, M.Inst.C.E. (chairman of the Company), presiding.

The SECRETARY (Mr. H. S. Hodgson) having read the notice calling the meeting,

The CHAIRMAN, in moving the adoption of the report and accounts, said: Gentlemen, this is the first meeting of the shareholders which has been called for any specific purpose. I would remind the shareholders that this Company was formed for combining, as far as might be found practicable, the tramway service and the electric lighting of Kidderminster and district. You are aware that there is a company called the Kidderminster and Stourport Electric Tramway Co. That company possess a line of tramways between Stourport and Kidderminster, and it is in contemplation to make an extension of it to Bewdley. I am glad to say that we are on extremely friendly terms with the Corporation of Kidderminster, who, although they have not seen their way to support our proposition exactly in the form in which we put it before them, yet have come to an agreement with us whereby they will withdraw all opposition, so far as they are concerned, to the granting of the requisite Order. This Company made an arrangement whereby they took over the electric lighting Order granted to the Corporation of Kidderminster, and in order to work the whole undertaking economically the two enterprises—the tramway service and the lighting—have been combined as far as possible. You will notice by the accounts that this Company hold 5,600 shares of £10 each of the Kidderminster and Stourport Electric Tramway Co. out of the 5,720 shares issued, and had paid up, on Dec. 31, £22,400 on account of calls due on those shares. Other money has been spent on capital to the extent of £6,676 in connection with buildings and plant for electric lighting, and I may add that there is every prospect that the supply of current will be commenced in the course of the coming summer. The revenue account shows, you will see, that the revenue of the Company (£1,558) is almost entirely derived from the dividend receivable from the Kidderminster and Stourport Electric Tramways Co., and, on the other side, you will notice that we carry forward a balance to net revenue of £1,448. The only amounts which have been spent by way of management expenses are £32 odd for stationery and printing, and £52 odd for general establishment charges, so that the total expenses of managing the business during the past eight months have been just over £84, apart from a special outlay of £16 for obtaining a Stock Exchange quotation. There remains a net profit of £1,458, which the Directors propose should be applied as follows: To dividend on cumulative preference shares £312, and to be carried forward to the next account £1,145. Although we are not individual shareholders in the Kidderminster and Stourport Electric Tramway Co., our company hold the great bulk of the shares, and therefore it has been decided, in order to more clearly show the manner in which that property has been managed, to enclose with the Directors' report and the accounts of this company a copy of the balance-sheet and the profit and loss account of that company. There is only one item in those accounts which calls for comment, and that is sundry creditors, £34,423. This sum is a large one, but it was dealt with fully in the prospectus on which the capital of this Company was raised, and I may say that the whole of the amount, with the exception of £7,000, has now been wiped out. Turning to the profit and loss account of the Kidderminster and Stourport Co., the traffic receipts amount to £5,335, which, with advertising and sundry receipts, brings the total up to £5,537. The power and running expenses were £2,688, repairs and maintenance £341, and administration and general expenses £341, leaving a net balance of £2,165. The Directors regard this result, considering the circumstances of that undertaking, as highly favourable, and they believe that when the Bewdley line is added, thereby considerably reducing the average rate of expenses over the whole system, a very much improved profit will be shown. I now move the resolution.

Mr. C. SHIRREFF B. HILTON seconded the resolution, which was carried unanimously.

On the motion of Mr. STEVENS, seconded by Mr. HOWARD SMITH, the retiring Directors, Mr. Emile, Garcke and Mr. Hilton, were re-elected. and the auditors, Messrs. Walter J. Kershaw and Co., were also re-elected.

The proceedings concluded with a vote of thanks to the chairman.

Oriental Telephone and Electric Co. (Ltd.).

The sixth ordinary general meeting of this company was held on Wednesday, Sir AUCKLAND COLVIN, K.C.S.I., presiding.

The SECRETARY (Mr. Alexander B. Chalmers) read the notice convening the meeting, and the report and accounts were taken as read.

The CHAIRMAN said: Gentlemen, it gives the Directors great pleasure to meet the shareholders again with so satisfactory a report. Increases all round have been attained both in the numbers of subscribers at the different centres and in the receipts, whilst the expenses are but in proportion to the heavier work entailed. After providing for the usual dividend of 5 per cent., there is therefore a balance to be dealt with of £4,507. 16s. 10d., as compared with £3,344. 8s. the year before. The board hope that their proposal to add a larger amount to the reserve fund than on previous occasions will commend itself to the shareholders. Much re construction of an expensive nature, necessitated by the increase of business, is now taking place in the localities where the company's operations are carried on. During the present year the old reserve fund, now available only for capital expenditure, will have to be drawn upon to a considerable extent, and it is therefore desirable that the new reserve fund should be brought up to a fair strength so as to become available again for all and any purposes whenever necessary, such as was the case in former years. Whilst the Directors believe that the best interests of the company are served by this policy, they are pleased to add that should the steady development of the company's business render it desirable, an increased dividend might possibly be recommended at a later date, when this question again comes up for consideration. The closing of the Shanghai exchange is a matter of regret. The Municipal Council imposed on the China Co. conditions which would have involved an expenditure of fresh capital to the extent of from £15,000 to £20,000. This sum would have had to be provided by this company, but we have come to the conclusion that better and safer employment can be found for so large an amount in our exchanges nearer home, especially in Egypt. The Hong-Kong branch, on the other hand, is prospering, and is sufficiently provided with funds for a considerable time to come. Indeed, we hope that that branch will be in a position next year to contribute to our annual dividend. I now move the adoption of the report and accounts.

Mr. THOMAS LLOYD seconded the motion, which was unanimously agreed to.

Resolutions approving the dividend of 8d. per share, free of tax (making 5 per cent. for the year 1899), and re-electing the retiring Directors and auditors were passed, and a vote of thanks to the Chairman and Directors terminated the proceedings,

---

BUENOS AYRES AND BELGRANO ELECTRIC TRAMWAYS CO. (LTD.)—Mr. J. B. Concanon presided at the annual meeting of this Company last week. The accounts represented a mixture of horse and electric traction, and it was next to impossible to separate the profits of each section. Up to Feb. 16 last year only one section of the new line (Retiro Station to Palermo Park gates) was being worked electrically, but upon that date the line was continued from the Retiro Station to the Plaza, and on April 22 following the line was open from Palermo Park outwards to Belgrano, the inner loop in Belgrano being opened on July 4. The receipts per mile (9¼d.) were on the whole satisfactory, but, on the other hand, the expenses were for an electric line abnormally high. They made the initial mistake of running far too generous a service on some of the sections, and therefore at the commencement of the year they reduced it, and that caused a considerable saving in the expenses for wages, electric current, &c. The consumption of current, which they took under contract from a local company, was unusually high, due to the fact that the cables for feeding the overhead wires were in an incompleted state. The average consumption of current per mile run for 1899 was 1·3 of a unit. This figure they had already got down to 1·2, and when the feeder system was in full operation they hoped to get it down to about one unit per mile run, and having regard to the high rate of speed at which the cars travel, this might be regarded as a fair average. They were allowed to run at something like 15 miles an hour between the various points. The debit of £3,300, balance of 1898 power account, was occasioned by the contract entered into by Mr. C. Bright with the electricity supply company, whereby he guaranteed a minimum consumption of current, and their requirements having fallen short of that minimum, they were compelled to pay the sum in question. On Jan. 21 last they started running electric cars over the old lines from Belgrano, as far as the Park Gates, and on the 14th ult. a further section, as far as Centro America was similarly worked by electric cars. They were pushing on with the work of completing the conversion of the remaining and the most profitable portion of the old lines within the city, and they had reason to hope that the lines throughout their system would be open for traffic by July.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION (LTD.)—An extraordinary meeting was held on Tuesday to pass resolutions increasing the capital of the company to £800,000 by the creation of 30,000 new ordinary and 60,000 new cumulative 4½ per cent. preference shares, both of £5 each. Mr. W. F. Fladgate presided, and explained that the increase of capital represented the largest amount the directors considered, under any circumstances, would be required for the purposes of the company, whether for its old districts or for the city. On Dec. 31 last they had in their old districts the equivalent of 19,000 8 c.p. lamps connected and had capacity to supply was, therefore, necessary that they should provide a new station or possibly two, and increase their generating plant and apparatus at their existing stations, where they had facilities for so doing. The company anticipated having to spend, between now and the next five years, not less than £250,000 to enable them to cope with their business. They had expended in round figures £500,000, and required £250,000 further expenditure on stations and works, and they propose to expend in the city about £200,000, making in all £950,000. They were already lighting 1,300 8 c.p. lamps within the city area, which he thought was a good beginning. They proposed to register a new company to lay mains, and to provide the installation for the City, and to that company they would loan the necessary moneys, and would take shares in the company to the extent of the money so advanced. He had no doubt whatever that they would reap a rich harvest from their City business. The new shares would be issued to the present shareholders *pro rata*, at a premium slightly under the present market value. The resolutions submitted to the meeting were approved unanimously.

NEW COMPANIES, STATUTORY RETURNS, &c.

BRAZELESS JOINT CO. (LTD.)—This company was registered on April 12, with a capital of £20,000, in £1 shares, to carry on the business of electricians, electrical and general engineers, machinists, &c.

JOHNSON-LUNDELL ELECTRIC TRACTION CO. (LTD.)—This company was registered on April 17, with a capital of £300,000, in £5 shares, to acquire any patents and rights relating to the generation, storage, and use of electricity, and in particular to acquire from Messrs. E. H. Johnson and R. Lundell certain patents for improvements in dynamos, electric motors and apparatus for controlling electric currents, electric railways, &c. The subscribers are L. W. Holmes, electrical engineer; E. H. Johnson, electrical engineer; T. M. Winstanley-Wallis, electrical engineer; A. Holmes, electrical engineer; J. H. Holmes, electrical engineer; A. Laing, and S. E. Robson. The first directors are G. B. Hunter, A. Laing, L. W. Holmes, E. H. Johnson, and H. Webb.

SMITH BROTHERS AND EASTWOOD (LTD.)—This company was registered on April 21st, with a capital of £35.000 in £1 shares (32,000 preferred ordinary and 3,000 deferred ordinary), to acquire the business carried on by Smith Brothers and Eastwood, and to carry on the business of mechanical, electrical, and general engineers, &c.

W. F. STANLEY AND CO. (LTD.)—This company was registered on April 10, with a capital of £120,000 in £5 shares, to enter into an agreement with Mr. W. F. Stanley for the acquisition of the business of manufacturers of and dealers in optical, geodetic, surveying, mathematical, drawing, and philosophical instruments carried on by Mr. Stanley, at Great Turnstile, Holborn, W.C., Railway Approach, London Bridge, S.E., and Victoria-street, S.W., and the factories at Great Turnstile and 8 and 9, Tichborne-street, W.C., and the optical works at South Norwood, with goodwill, stock-in-trade, trade marks, machinery, fixtures, utensils, copyrights, letters patent, secret processes, drawings, designs, models, contracts, &c., to develop and extend the said business, and generally to carry on the businesses of workers of and in, merchants and contractors for, articles made of metal, wood, ivory, glass, or other materials, &c. The signatories are W. F. Stanley (1,000 shares), G. I. Gray (50 shares), T. S. Walker (20 shares), O. G. Winzar (20 shares), H. T. Tallock (50 shares), J. Austin (10 shares), and A. G. Bennett (5 shares). The first directors are J. Stanley, W. F. Stanley, G. I. Gray, and W. W. Cobbett.

BARCELONA TRAMWAYS (LTD.)—The annual return to April 4th has been filed. The capital is £300,000 in 20,000 ordinary and 10,000 preference shares of £10 each, all of which have been taken up and paid for in full.

CITY OF LONDON ELECTRIC LIGHTING CO. (LTD.)—The annual return to March 29th gives the capital as £1,200,000 in 40,000 preference and 80,000 ordinary shares of £10 each, of which 40,000 preference and 60,000 ordinary have been taken up. £10 has been called up on each share and £1,000,000 has been received.

ELECTRIC SIGN AND GENERAL ADVERTISING CO. (LTD.)—The annual return to February 23rd has been filed. The capital is £5,000 in £1 shares, 2,000 of which have been taken up. £1 has been paid on 1,000 shares, the remaining 1,000 being considered as fully-paid.

METROPOLITAN ELECTRIC SUPPLY CO. (LTD.)—The annual return to March 27th has been filed. The capital is £1,000,000 in £10 shares, 85,000 of which have been taken up. £10 has been called up on 82,968 and £829,680 has been received, 2,032 shares are considered as fully-paid.

OLDHAM, ASHTON AND HYDE ELECTRIC TRAMWAY (LTD.)—The annual return to March 22nd gives the capital as £80,000 in 4,000 ordinary and 4,000 preference shares of £10 each, all of which have been taken up and paid for in full.

POTTERIES ELECTRIC TRACTION CO. (LTD.)—In the annual return to April 2nd, the capital is given as £400,000 in 20,000 preference and 20,000 ordinary shares of £10 each, all of which have been taken up. £10 per share has been called up on 20,000 preference and 13,334 ordinary shares, and £333,340 has been received, 6,666 shares are considered as fully-paid.

SCARBOROUGH ELECTRIC SUPPLY CO. (LTD.)—According to the annual return to March 5th, the capital is £50,000 in £10 shares, all of which have been taken up, and £9 per share called.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER CO. (LTD.)—The directors have issued a circular to the shareholders regretting that the delay in the arrival of the balance-sheet relative to the suspension of Dumbell's Bank has placed the company in an extremely difficult position, rendering it necessary to call in Messrs. Turquand and Youngs to prepare a statement of the affairs of the company.

NOTES.

AMONG the electrical bills now before Parliament, that of the Baker-street and Waterloo Railway Co. deserves notice. By this bill powers are sought to extend the railway underground from the Marylebone terminus of the Great Central Railway to the Paddington terminus of the Great Western Railway, and at the other end of the underground line to extend from Waterloo to the Elephant and Castle. These additions to the originally proposed length of the line involve about 2¼ miles of additional route. Subways would, of course, be constructed connecting with the main railway termini mentioned. Sanction is also sought to erect the power station on the site of the school belonging to the trustees of the Indigent Blind in St. George's, Southwark, and no local opposition, it appears, has been raised to the erection of a generating station on this spot. The additional capital to be raised by shares is £1,000,000, with further borrowing powers of £333,000. In view of the great facilities thus afforded by the railway, as now proposed, for passenger communication between several London railway termini, as well as on account of the relief it would afford to street traffic, it seems highly desirable that these powers should be granted by Parliament without delay.

IN the debate on the telephone question in the House of Commons last Friday, two separate questions were raised. One was whether the Post Office was acting rightly in laying inter-exchange cables for the National Telephone Co. in Glasgow in accordance with the agreement made at the time of the cession of the trunk wires—even if the Glasgow Corporation desired that the Department should ignore this agreement. The second question was with regard to the way-leave controversy in London, referred to in our last two issues. In spite of Mr. HANBURY's repeated assertions last year that he desired to act with absolute fairness and impartiality to the company, he supports the London County Council in its unreasonable demands.

IT is, we believe, without precedent in the annals of the Institution of Electrical Engineers that a writer, in acknowledging the source from which a large part of his Paper is taken, impugns the accuracy of that source in the same sentence. Prof. GEORGE FORBES has taken the first part of his Paper, which will be found elsewhere in this issue, from the technical journals, which, he says, "are always liable to mislead, especially as to the satisfactory nature of the supposed uninterrupted supply of power." Our readers need not to be told that such statements are not borne out by fact—at all events, so far as our columns are concerned; but, for Prof. FORBES's benefit, we may refer as specific examples to two of the plants mentioned in his Paper. Our description of the Paderno-Milan power transmission was not taken from a French journal, as was Prof. FORBES's, but was written by the engineer who designed and erected the station. For details of the Rheinfelden plant, Prof. FORBES refers to a book describing the original scheme before the plant was completed, but since the publication of this volume the scheme was considerably modified, and in *The Electrician* he would have found a detailed description of the plant written by our correspondent, who had examined and discussed almost every detail of it with the engineer responsible for its erection and subsequent maintenance. Among the descriptions of the Niagara plant published in all the electrical journals, was a Paper by Prof. FORBES himself, who, we believe, takes credit for its design and erection. This, indeed, was "liable to mislead," as it was merely a description of plans and specifications. As to interruptions of supply after plants have been in operation—to which the Professor seems to attach such importance—our columns contain particulars of these whenever they are of technical interest.

NO ONE will deny that there is room for improvement in the British patent system, especially in the direction of reforming and rendering less costly the methods of settling disputes, and

Digitized by Google

in amending the procedure by means of which the patents themselves are "amended." But although reforms are needed, we should be sorry to see such sweeping ones as are recommended by Mr. IVAN LEVINSTEIN in a pamphlet lying before us, which has been "approved and adopted by the Board of Directors of the Manchester Chamber of Commerce." It is surprising to find so important a body as the Manchester Chamber of Commerce identifying itself not only with Mr. LEVINSTEIN'S extreme views, but with a polemic in which the present patent system is criticised and its drawbacks magnified in no impartial spirit.

THE criticism is chiefly devoted to the absence of preliminary examination by the Patent Office as to novelty, when an inventor desires to patent an invention. First, we are introduced to the "poor inventor, who may have deprived himself of the necessaries of life in order to scrape together the money needed for paying the fees demanded by the Government . . . ,"—fees which, Mr. LEVINSTEIN forgets to add, would be higher if the Government were called upon to make a preliminary examination. "He (the inventor) presently finds out that what may have been the dream of his life may have been patented 10 or 20 years before by probably 50 other poor inventors." But is it not reasonable to expect the poor inventor to devote a few hours of the lifetime, which would otherwise have been wasted in dreaming, to examining the records of the Patent Office—an examination which has been recently greatly facilitated by additional indexing—and ascertaining for himself whether he has not been anticipated? Next, the writer of the pamphlet refers to "the injury suffered by really meritorious inventors, and the trading interests of the country alike" by inventions existing on paper only. To illustrate this, he alludes to the fact that in organic chemistry "you may by theoretical deduction fix the potential existence of a large and almost unlimited number of substances, which may never have been seen or made by anyone," and instances a certain patent covering "thousands of possible colouring matters," which "it will take an expert chemist in his laboratory several years to produce." But surely this patent would not be valid, for, according to existing patent law, an inventor has to give explicit instructions in his patent to enable any person of ordinary skill in the art to construct the apparatus or material for which protection is desired. Again, it is more than a slight exaggeration to say that "A British patent is only considered of value after having passed through the ordeal of a most expensive law-suit."

IT is tedious to be constantly told that we must remodel all our institutions to conform with the German pattern; and we will not allow that Germany is so immeasurably our superior in the case of patent law as Mr. LEVINSTEIN maintains. In holding up the American patent procedure as being less free from abuse than our own, however, Mr. LEVINSTEIN must be under a misapprehension.

IN commenting on the report of the "Committee on Copper Conductors," in our issue of December 22nd last, we expressed surprise that a value for "MATTHIESSEN'S Standard" of the resistance of pure annealed copper wire should have been chosen differing from that generally accepted. Prof. J. D. EVERETT writes in our "Correspondence" columns this week that he has been unsuccessful in finding the Committee's standard in any of Matthiessen's own Papers or reports. In reply, Mr. A. H. HOWARD gives chapter and verse for the standard chosen; but on looking up the reference we find, not a report of Dr. MATTHIESSEN or of Prof. FLEEMING JENKIN, but a table reprinted in a report of some Cantor lectures on submarine telegraphy delivered by the latter gentleman in 1866. The table is headed "Specific Resistance in B.A. units of Metals and Alloys at 0° Centigrade, from Dr. MATTHIESSEN'S Experiments," and bears the footnote:—"This table has been considerably modified, both on account of some clerical errors, and on account of the use of different specific gravities," so that it is evidently not MATTHIESSEN'S actual figures that are given. Mr. HOWARD'S reference to the varying values given for the specific gravity of copper only emphasises the arbitrary nature of the report, for the committee has chosen the value 8·912 merely because it is the equivalent to 555lbs. per cubic foot.

Obituary.—The death is announced of Prof. Silas W. Holman, Emeritus Professor of Physics at the Massachusetts Institute of Technology.

The American Association for the Advancement of Science.—The annual meeting of this Association will be held at Columbia University, New York, from June 25 to 30 inclusive.

Electrical Organ Blowing.—A new Hope-Jones organ in the Burton parish church was dedicated last week. The organ-blower is driven by an alternating-current motor connected to the public supply mains.

Fire.—A small fire at Lord Battersea's house in London, last Friday, is attributed to a defective new installation of electric light in one of the rooms, which was apparently switched on without being properly tested beforehand.

Importation of Electrical Apparatus into Turkey.—A Reuter's Constantinople telegram, on Monday last, stated that the Sultan has issued an Iradé prohibiting the importation into Turkey of all electrical apparatus, "including electric bells."

Little Scheidegg-Männlichen Electric Railway.—The Jungfrau Railway Co. intends to build a branch line from the Little Scheidegg to the top of the Männlichen. This line will be 2·6 miles long, and its estimated cost will be £16,000. The elevation of the Little Schiedegg is 6,770ft. above the level of the sea, and that of the top of the Männlichen 7,700ft., the maximum gradient being 6 per cent.

The Ottawa Fire.—According to the Ottawa correspondent of the *Standard*, new electric plant has been installed in Ottawa. The cars were running and buildings and residences were lighted up on the day after the fire, *i.e.*, on Friday last. This fact is all the more remarkable that the readers of the newspaper accounts of this disastrous fire will remember the Ottawa power-house is stated to have been burnt down.

Electric Railway to Oberammergau.—The line between Murnau and Oberammergau has been opened, but owing to the bad weather the erection of the electrical equipment has been delayed, and the trains are at present being drawn by steam locomotives. It is hoped, however, that the electric installation will be ready before the Passion Play takes place. The line, which is being built by Messrs. Kummer, of Dresden, is 15 miles long, and has several gradients, the largest of which is 3 per cent., extending over a length of nearly four miles.

Technical Education Board Scholarships.—The Technical Education Board of the London County Council will shortly award five senior county scholarships of the annual value of £60, with free tuition fees up to £80 a year. Candidates must not be more than 22 years of age, and their parents' incomes must not exceed £400 a year. The scholarships are tenable at some university or technical college of university rank. Application forms may be obtained from the secretary of the Technical Education Board, 116, St. Martin's-place, W.C.

Electroplating from Non-Aqueous Solutions.—In a recent Paper before the Chicago Electrical Association, Mr. C. F. Burgess referred to the desirability of a bath containing no water, which would obviate difficulties experienced with certain metals owing to the liberation of hydrogen from the water. It is possible to dissolve certain metallic compounds in certain organic substances containing no water, and such solutions may act as electrolytes. Dr. Kahlenberg, of the University of Wisconsin, has succeeded in obtaining good deposits of lithium by such a method, and lithium is, in ordinary circumstances, more difficult to deposit than aluminium or magnesium. His method consisted in dissolving lithium chloride in pyridine, and electrolysing in the ordinary way.

An American Pacific Cable Bill Passed.—The *Electrical World* of America says that on April 11, the Senate passed a bill appropriating a sum of $3,000,000 for the construction and laying of a cable between San Francisco and Honolulu, the work to be done under the supervision of the Navy department, who have surveyed the routes. The bill provides that any ships, American or foreign, may be used in the laying of the cables. In the event of the Navy department deciding to accept tenders from other contractors for the complete work, a clause in the bill provides that the cable, wires and other necessary instruments, materials, appliances and appurtenances shall be manufactured in America, provided that the cost do not exceed by more than 12 per cent. the cost of same in any foreign market. Americans are surely paying a high price for their independence!

The Telephonograph.—This instrument, which is a modification of the phonograph, was recently inspected and tested by the German Postmaster-General and several engineers. Its inventor, Herr Paulsen, a Dane, has replaced the wax cylinder of the Edison phonograph by a steel band, and the style by a magnet energised by a telephone. Currents transmitted by the telephone pass through the electromagnet and create consequent poles on the steel band, and more or less the converse operation is employed for reproducing the sound. A long line can, of course, intervene between the transmitting telephone and the phonograph itself, and it is suggested that a telephone subscriber on leaving his office can set such a telephonograph to receive telephoned messages during his absence. Even if the efficiency of the instrument is only twice that of the average office boy, it should find many purchasers. We understand that the apparatus will be shown in operation at the Paris Exhibition.

A New Typewriting Telegraph.—A new typewriting telegraph, the invention of Mr. W. S. Steljes, formerly an electrical mechanician in the Post Office, is about to be put on the market by the Typewriter Telegraph Corporation (Ltd.), the prospectus of which will shortly be issued to the public. The capital of this new company is fixed at £100,000, the chairman being Sir James Ferguson, Mr. C. E. Spagnoletti acting as consulting engineer. The instrument, which is of simple construction, requires no battery power, the electrical energy being generated by a magneto-instrument, as in the Wheatstone A B C transmitter. In working the instrument a record is made at both ends of the line in the form of a printed copy of the message sent, and, as it can be used in conjunction with telephone lines, both verbal and printed messages can be sent. It is stated that the instrument, which can be worked on single lines of great length, is safeguarded against the possibility of tapping for intercepting messages.

Institution of Electrical Engineers.—At the meeting of the Institution, on April 26th, the President (Dr. S. P. Thompson) in announcing the list of nominations for President and Council for 1900-1901 (published in our last issue) read Article 45 of the Articles of Association, which provides that the Council shall, at least 28 days before the annual general meeting, announce the names of members whom they propose as officers and Council for the ensuing year. Alternative names may be proposed by any two members, supported by eight other members; but the proposal, together with the written consent of the new candidates, must be sent in to the Secretary within seven days of the Council's announcement. If no other candidates are put forward, those proposed by the Council are considered duly elected. Dr. Thompson also drew attention to the fact that M. E. Mascart, who is on the list of nominations for a Vice-Presidency, is to be President of the International Congress of Electricians, which will be held at the Paris Exhibition in August.

Canadian Water Power Development.—The Ontario Power Co. have definitely agreed, says the *Electrical World* of New York, with the Commissioners of the Queen Victoria Niagara Falls Park for the development of power on the Canadian side of the Niagara River. The company's plans contemplate the immediate development of from 30,000 H.P. to 60,000 H.P., which can be readily increased up to 300,000 H.P. The cost of the development of 30,000 H.P. is estimated at $2,000,000. It is proposed to bring the water from the Welland River at the point where it enters the Niagara River, by a canal to a bluff below the Dufferin Islands, where the first 60,000 H.P. will be developed. The water will be carried thence by an open canal through the park to a point just below Table Rock, where, under a head of 160ft., 240,000 H.P. will be available. The company expects to deliver the first power in about 18 months, and it will be used for electrolytic work and other industries, including a large steel plant, all of which will be located on the company's grounds, which comprise about 2,000 acres. It is stated that applications have already been filed for 60,000 H.P.

Underground Telephone Subways in Chicago.—The Illinois Telephone and Telegraph Co., in the underground system they are laying, are making a radical departure from the usual telephone practice. In Paris the telephone and telegraph cables are laid in troughs or suspended on hooks from the walls of the existing sewers, but this company is building special tunnels for the accommodation of its cables. The tunnels, described in a recent issue of the *Western Electrician* of Chicago, are of horse-shoe section, 8ft. in height with a maximum width of 6ft., and their floor is 38ft. below the centre of the roadway. No manholes are being made in the roadway, and communication with the tunnel is made by laterals running to the sidewalk, through which also the distributing wires are carried. Five shafts have been sunk and the excavations are being carried out under an air lock. The cables will be held on racks on the sides of the tunnel. The tunnels are lighted by means of 110 volt incandescent lamps, strung at 25ft. or 30ft. intervals along the top of the drifts, the current being derived from a generator in the basement. All the work at the heads of the drifts is done by the aid of electric lights, no torches being used, as they would be liable to cause explosions in gas pockets. The company is making experiments with an automatic telephone switchboard, and the precise nature of the exchange equipments has not yet been decided upon.

A Mercury Jet Interrupter.—In our issue of March 9, we described a new form of mercury jet interrupter recently brought out by Messrs. Isenthal, Potzler and Co. In a recent issue of *Nature*, Prof. S. M. Kintner, described another form

Digitized by Google

of such interrupter, giving a high frequency of interruption which could be accurately measured. His description is as follows:—

An iron vessel, arranged as a Mariotte flask to maintain a constant head, holding about a pint of mercury, formed one terminal and a metallic plate the other. The plate was arranged below the vessel, and the mercury fell upon it, completing the circuit. In the bottom of the flask was a row of 10 holes, arranged around in a circle, with nozzles fitted into them. On a vertical shaft, concentric with the row of nozzles, a series of mica sectors were arranged, so that, when revolving, they would cut the mercury jets falling from the vessel above. These strips were placed with the line of their edges parallel to the axis of the shaft. Thus they would break the circuit in several places at the same instant, giving a very sharp break. It was found better to break the circuit by interposing an insulator than to break by opening the circuit with a conductor, as the wear at the spark tended to keep them all equal, so they automatically adjusted themselves to the best positions. The object of the row of jets was to get a more rapid interruption. To break a single jet in five or six places simultaneously, and at the same time with a satisfactory frequency, was found to require too great a head and velocity of jet to be practicable, so by adopting a row of ten the frequency could be increased that many times. These jets are all in parallel, and when the mica strips are revolving the head is so adjusted, by the Mariotte flask arrangement and screws on the sides of the reservoir, that at the instant of interruption of one jet, all the others are in a state of interruption; but the one directly in front of the mica strips will be the first to make the circuit. Thus it continues to break at a rapid rate. Greater rapidity of break can easily be obtained by increasing the speed, by increasing the number of nozzles, by increasing the number of sets of mica strips, or by any combination of the three. This form of interrupter will be found quite useful to any one desiring a known rate, high frequency interrupter.

Relative Popularity of the Toll System of Telephone Charges.—From a German contemporary we learn that the larger proportion of telephone subscribers in Berlin have preferred the old tariff system of a fixed sum per year, and only about one-fifth (8,000 subscribers) have elected to be charged according to number of conversations. The latter class of subscribers include chiefly the small offices and shops, and it is considered that the attraction to them of this system of charging is that they are entitled to loan their telephones at the rate of 5pf. ($\frac{3}{5}$d.) per conversation. Doctors, lawyers, and private persons who have the telephone chiefly to enable others to call them up have naturally preferred this system also. The fixed rate system has been preferred by the owners of larger restaurants, hotels, cigar shops, &c. The Bavarian and Würtemburg post offices have followed the example set by the Imperial post office, and have also made the toll system optional. In Munich 516 out of 5,500 subscribers have chosen it, in Nuremberg 390 out of 2,800, in Augsburg 101 out of 580, in Würzburg 120 out of 580, in Fürth 88 out of 540, in Bamberg 43 out of 230, in Regensburg 81 out of 280, and in Landshut 2 out of 55.

German Meter Statistics.—Some interesting statistics as to the employment of electricity meters in Germany have been collected by the Physikalisch-Technische Reichsanstalt, and are published in the *Electrotechnische Zeitshrift* of April 5. Circulars requesting information were sent to nine firms of meter manufacturers and 950 central stations and private stations using meters. The makers estimated that on July 1, 1899, 126,000 meters were in use, while the central station and private station returns only totalled about 60,000—the difference probably being due to the number of meters in stock and not yet put into use, also those employed for various testing purposes, and those exported. During the year 1898 alone, no less than 20,000 meters were supplied by the various manufacturers. In some of the returns the size of the meters was specified, and from these, out of 30,000 continuous-current meters 70 per cent. were for currents up to 20 amperes, 28 per cent. from 20 to 100 amperes, 1 per cent. over 100 amperes and 1 per cent. for tramway systems. Out of 8,500 alternating-current meters (both single and polyphase) 68 per cent. were for loads up to 5 kw., 22 per cent. from 5 kw. to 10 kw., and 15 per cent. over 10 kw. In their replies to a question as to the permissible error, the makers and the larger supply stations were in agreement, but smaller works considered a greater degree of accuracy desirable and one that is not attained in practice. Of course, in all circumstances, the electricity meter is more accurate than the gas meter. According to the new law settling electrical units, the Physikalisch-Technische Reichsanstalt is empowered to frame rules for the official testing of meters, and in the circulars it requested the central station representatives to say how soon, in their opinion, such regulations should come into force. Of the 950 stations, only 175 answered this question. Forty-one (representing 15,100 meters) thought that the official testing would be too difficult to introduce, or that the meters or the testing offices had first to be improved upon, while only twelve works (representing 900 meters) replied "soon." Fifty-five works (with a total of 9,000 meters) suggested the year 1902, and the majority of the replies—from fifty-seven stations, owning between them 22,300 meters—named dates from 1903 to 1910.

Interruption of the Hull Tramway Service.—An unfortunate interruption of the electric tramway service in Hull, due to a breakdown of the generating machinery, took place on Friday last. It will be remembered that the plant, which was described in *The Electrician*, Vol. XLIII., p. 482, consists of two 300 kw. Belliss-Siemens two-pole direct-driven sets. There is also one spare armature in the station, and one similar set is completed, but has not yet been delivered from the maker's works. None of the three dynamos, however, nor even the spare armature, have as yet been accepted by the Corporation as fulfilling the conditions of the specification, although the plant has been running since last July. On Friday one of the sets was running from 4 a.m. to 6 p.m., when the two dynamo bearings seized, the white metal ran, and the armature was slightly damaged from cutting on the pole pieces. The load was immediately transferred, without trouble, to the other set, which ran till shortly after nine o'clock, when its armature blew out and stopped the service. Meantime the fitters were at work getting out the armature of the first machine to repair the bearings. On the second machine breaking down, however, the armature was changed as speedily as possible for the spare armature, but, owing to the latter being quite new, the bolt holes in the coupling had to be broached out by hand, and it was 11.30 p.m. before this had been finished and supply resumed. During the day the Tramways Committee held a meeting and deputed three members, with the Town Clerk and electrical engineer, to see the contractors, Messrs. Siemens Bros. and Co. at once, with a view to obtaining the delivery of the third engine and dynamo to guard against a repetition of the accident, and pending the settlement of the question of the final acceptance by the Corporation of the three machines. On Saturday evening another unfortunate stoppage for about an hour-and-a-half took place, owing to the insulation of a field coil breaking down. It is only just to Messrs. Siemens Bros., to say that their engineers worked hard and ungrudgingly to repair the damage as quickly as possible.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

MONDAY, May 7th.

SOCIETY OF ENGINEERS.

7.30 p.m. Ordinary Meeting at the Royal United Service Institution, Whitehall. Paper to be read: "The Economical Disposal of Town Refuse," by B. D. Healey.

THURSDAY, May 10th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting at the Society of Arts. Paper to be read: "A Frictionless Motor Meter," by S. Evershed.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture III.: "A Century of Chemistry in the Royal Institution," by Prof. Dewar, F.R.S.

FRIDAY, May 11th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Agenda: (1) Discussion of Prof. Lodge's Paper, "On the Controversy concerning Volta's Contact Force"; (2) "The Heat of Formation of Alloys, by J. B. Tayler; (3) "On the Want of Uniformity in the Action of Copper-Zinc Alloys on Nitric Acid," by Dr. Gladstone, F.R.S; (4) An Electro-magnetic Experiment and Experiments illustrating the Aberration called Coma, by Prof. S. P. Thompson, F.R.S.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Actinium.—By treating pitch blende with the reagents used for the extraction of metals of the iron group, and more especially of titanium and thorium, A. Debierne has succeeded in discovering a new radio-active substance, which has the general characteristics of thorium, but does not follow that metal through all its reactions. If a barium or bismuth salt is added to a solution of the new substance, the salt added may be eliminated by means of ammonia or sulphuretted hydrogen, without thereby eliminating the radio-activity. This proves that the latter is not due to either radium or polonium. The author calls the new substance "actinium." It produces the same phenomena of fluorescence, photographic action, and ionisation, as radium and polonium. All the experiments of magnetic deflection made by Giesel, Meyer, Schweidler, and Becquerel may be repeated with actinium. It also produces, to a slight extent, the permanent induced radio-activity described by Curie. It is known that the salts of thorium are feebly radio-active. The author suggests that their radio-activity may be due to traces of actinium, and that the latter is, in fact, the active principle of thorium radiation.

[A. Debierne, *Comptes Rendus*, April 20, 1900.]

Magnetised Coherers.—In the course of some experiments in wireless telegraphy made between Brest and Ouessant, C. Tissot hit upon a device which considerably increased the sensitiveness of the nickel or steel coherer used, and at the same time made it work with greater regularity and certainty. The device consists in placing the coherer in a magnetic field whose lines of force are parallel to the axis of the tube. The latter should contain some kind of magnetic filings, steel, nickel, or cobalt. The electrodes should preferably be non-magnetic, and the tube may be placed between the polepieces of an electromagnet feebly excited. The first result observed is that the terminals may be drawn very much further apart without annulling the action. The distance may, in fact, be increased from 1mm. to 6mm. Both the current traversing the coherer and the magnetic field controlling it should be feeble, as otherwise the decohering action is interfered with. One of the most striking results was the exchange of signals with the warship "Massena," over a distance of 18 nautical miles, with signalling masts only 100ft. high. The action of the magnetic field appears to be purely mechanical. It is important on account of the ease of regulation which it introduces, even in the case of sealed tubes, whose sensitiveness can easily be brought to the point required. When the field is suddenly withdrawn, a very slight shock suffices to decohere the apparatus. This suggests the possibility of working the magnet by a relay, and thus securing automatic decoherence.

[C. Tissot, *Comptes Rendus*, April 2, 1900.]

Electric Lines of Force.—A good photographic tracing of electric lines of force may, according to W. Schaffers, be obtained in full daylight by the action of the secondary circuit of an induction coil upon a sensitive plate. Two needles form the terminals of the circuit. One of them is placed in contact with the sensitive film of a silver bromide or (better) lactate plate, while the other is held about half a millimetre above the surface some distance off. The former should be made the positive, and the latter the negative terminal. If both points are in contact with the plate, the wandering globules discovered by Leduc interfere with the tracing. The lines of force begin to trace themselves by a great number of small black lines resembling arrows, which point from the positive to the negative pole, and which under the microscope resolve themselves into a mass of ramifications. The traces are not dissolved by "hypo," and hence the plant may be made transparent and used as a negative. No developer is required as the traces appear at once in black. Quicker action may be obtained by diminishing the proportion of gelatine in the film. The formation of the traces commences with the fusion of the silver salt, and the blackening is due to the carbonisation of the gelatine. After a while, the bromide is reduced also. Gold iodide gives brown continuous tracings communicating with each other by numerous branches. Sometimes their formation is almost instantaneous. But these traces cannot be fixed.

[W. Schaffers, *Comptes Rendus*, April 2, 1900.]

Electric Waves between Bitumen.—C. Gutton has examined the question as to whether electromagnetic waves, when propagated through a medium whose dielectric constant is different from unity, have the same velocity when they are propagated freely through it, and when they are guided by a wire. For the experiments, he used the same apparatus as for his experiments on electric wire-waves (see *The Electrician*, Vol. XLIII., p. 864). A block of bitumen, 1m. long, was balanced against another of exactly the same size, but having a wire embedded in it through which the waves in the second circuit were propagated. The waves of the first circuit were sent through the free block by means of cylindrical parabolic mirrors. When the rates of propagation are the same, the two wave systems interfere with each other and produce no effect on the coherer which bridges the two circuits at a distant point. Such was actually the case, and the speed of propagation must, therefore, be regarded as independent of the presence of the wire. The same arrangement allows of the determination of the refractive index of the material for Hertzian waves. Compared with air, the refractive index of bitumen comes out as 1·870 without the wire, and 1·885 with the wire. The author considers that the small discrepancy here indicated is probably due to a lack of perfect identity of structure in the two specimens of bitumen, though it would, of course, be more satisfactory to have this made evident by further experiments on different specimens.

[C. Gutton, *Comptes Rendus*, April 2, 1900.]

A New Source of Error.—While determining index corrections of the compass declinometers belonging to the United States Coast and Geodetic Survey, G. R. Putnam observed motions of the magnetic needles of such a nature as to leave no doubt that the glass covers of these instruments carried strong electrostatic charges, caused by atmospheric conditions, which at the time were especially favourable, the weather being dry and cold. In two of the declinometers, in which the glass covers were replaced by brass plates, with only small pieces of glass covering the openings through which to observe the points of the needles, no erratic movements were noticed, and repeated determinations of their index corrections agreed with each other within the error of observation; while before, nearly all observers using these instruments reported occasional discrepancies in their results which could not be accounted for. In reporting upon this source of error, E. G. Fischer raises the question as what may be the effect of the same phenomenon upon the magnetic needle in other instruments. The theodolite magnetometers do not seem to be sensibly affected, but in the dip-circle, the manner of housing the magnet is such as to immediately raise the question whether the frequent want of accord between the results obtained may not be due to electrostatic disturbance. As a remedy, both sides of the magnet case should be of brass, and should be so arranged that they can be rotated about the axis of the needle, in order to bring the openings opposite the points. In any case, wherever glass must be used in magnetic instruments, it should contain a large percentage of lead.

[E. G. Fischer, *Terr. Magnetism*, March, 1900.]

Combination of Large American Electrical Companies.—According to the *Western Electrician* of Chicago an arrangement has recently been concluded whereby the Siemens and Halske Electric Co. of America is in future to be controlled by the General Electric Co. of New York. It is understood that, for a time at least, the former company will be worked independently. The merging of these two interests leaves but two companies in America manufacturing machines of the largest size—say of 1,500 kw. and over.

A MODERN GERMAN CENTRAL STATION.

BY JOHN R. DICK, B.SC.

German practice in public electricity supply has developed in somewhat different fashion from that which prevails in England. The great majority of the earlier undertakings were controlled by private companies, who obtained concessions of the rights of supply on more or less favourable conditions. Of recent years, however, after the profitable nature of these enterprises was recognised, the corporations of many towns are establishing municipal electricity supply works.

An admirable example of these municipal stations is that at Dortmund, which the writer has had the opportunity of inspecting closely. It presents many points of interest and

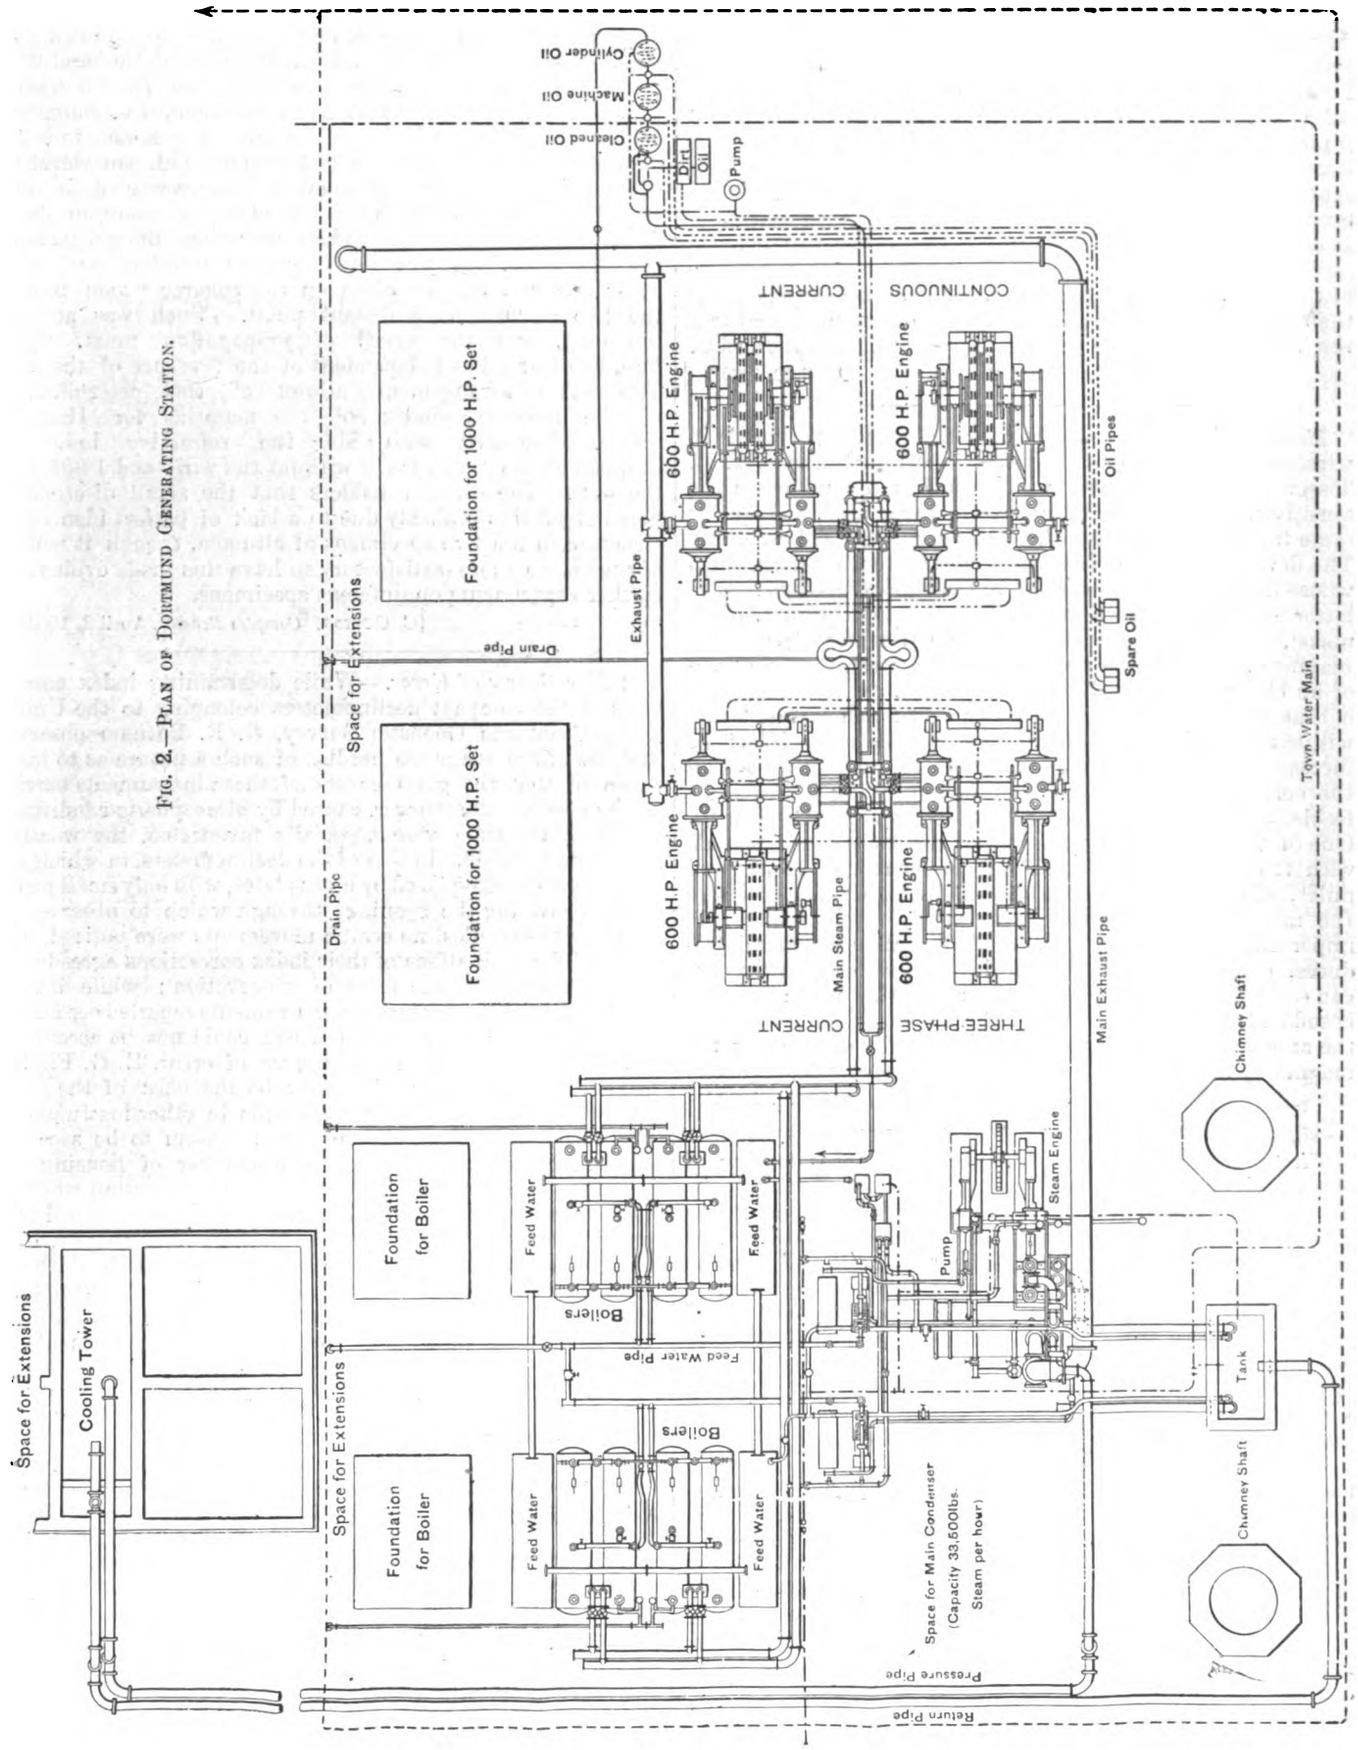

FIG. 2.—PLAN OF DORTMUND GENERATING STATION.

Digitized by Google

novelty in its design, as well as in the successful results it has achieved commercially. The town itself, with a population of 140,000, is situated in the highly industrial province of Westphalia, in close proximity to some of the best coal fields in Germany. It consists of two parts—a densely populated central area, and a series of scattered suburbs devoted to engineering and various manufactures. Perhaps the town is best known by its excellent Dortmunder beer, deservedly renowned all over Germany. In the urban area electricity is supplied by continuous current, while in the outer zone three-phase distribution is used both for light and power. The general methods of distribution with battery sub-stations, numerous short feeders, bare neutral distributors with bare neutral wires in the houses, are well worth consideration, as they differ so widely from English practice. The very general employment of motors and the large amount of electricity supplied for motive power are also noteworthy. The whole of the works were designed by the present manager, Herr Döpke, and built under his supervision.

The works at Dortmund were built in a remarkably short time. From the commencement of the work till the supply to 80 installations was turned on, there intervened a period of only nine months, yet the idea of having works on a large and commercial scale adapted to any reasonable future developments was not lost sight of. It was found from the statistics of 50 electricity works in operation in Germany that the output for light and power increased more than 20 per cent. yearly. Costly extensions were, therefore, very soon required. Bearing these facts in mind, the engineer at Dortmund decided to arrange for extensions of buildings and plant on a consistent and definite plan to meet the probable demand of the next 25 years. Arrangements have been made for doubling, or even trebling, the present capacity of the works without any alterations to the buildings. Of course in such a case the initial capital costs for this item are rather high; but, considering that additional plant will so soon be necessary, there is no doubt that the interest and sinking fund will be less than the additional cost of subsequent alterations to buildings. Some

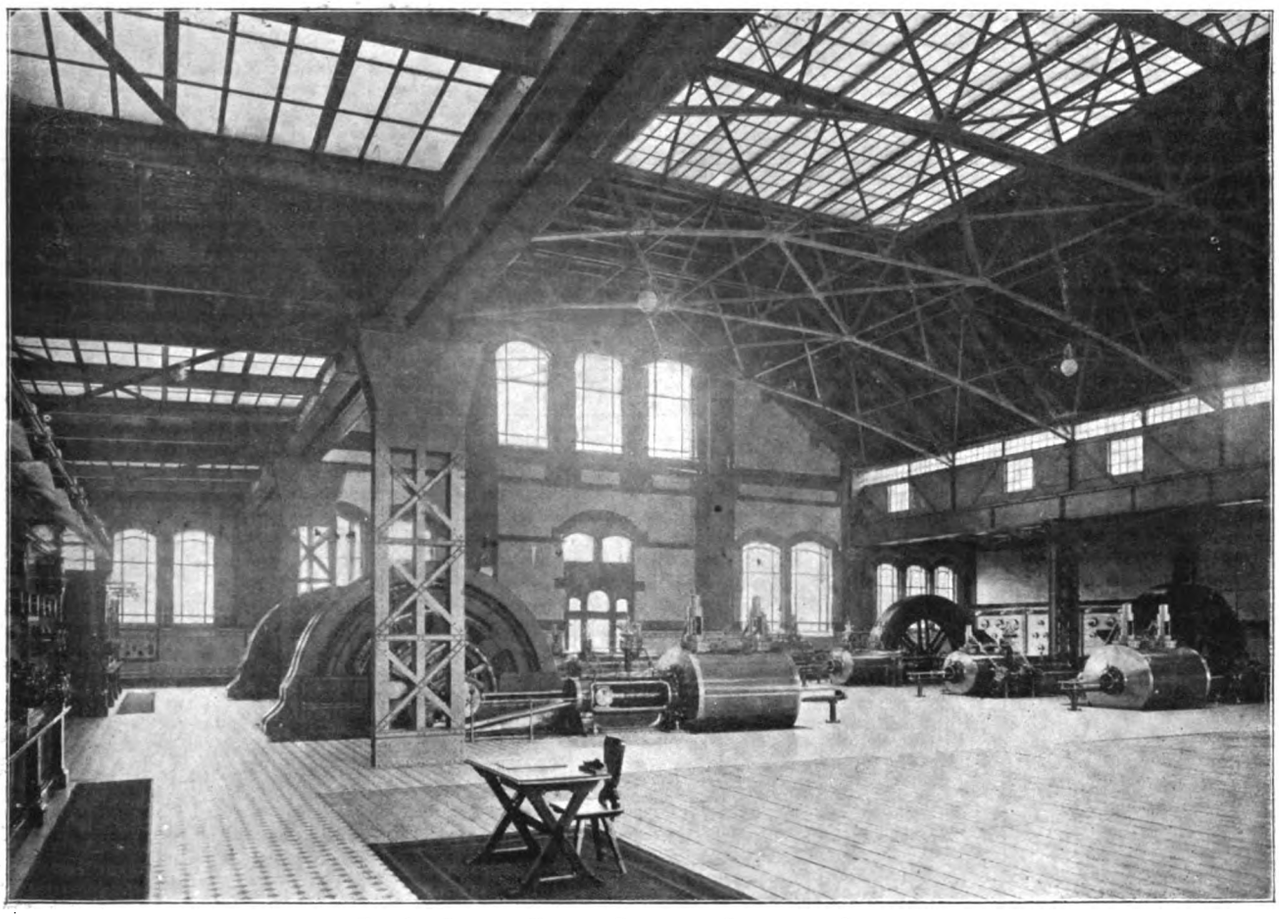

Fig. 1.—General View of Dortmund Generating Station.

A consulting engineer in Germany is more or less of a *rara avis*, as most of the stations are designed and equipped by the great manufacturing and financial companies, or, as in this instance, by the engineer who subsequently manages the business of supply. Under such conditions the municipality is likely to put more confidence in the recommendations of its engineer, and not to allow excessive caution or parsimonious ideas of initial cost to curtail the usefulness of a newly-started station. Municipalities in Germany do not make the mistake of imagining they are venturing on a precarious experiment in establishing electricity works. On the contrary they are regarded as solid and permanent undertakings that are certain to pay with good management. Accordingly they are designed on liberal lines, with ample buildings, and mains of sufficient section, so that the engineer is not continually preparing plans for niggardly extensions, to the exclusion of other duties. He has abundant opportunities for acquiring profitable business and for extending the use of electricity in the town.

engineers, when their works are barely completed, boast that their undertaking has been so successful that immediate extensions are required. This is a state of things entirely to be deplored instead of applauded, as it proves how, with a little foresight, a large expenditure might be saved. Extensions to buildings while running the station endanger the continuity of supply, occasion serious inconvenience, and are comparatively more costly.

The spacious engine room shown in the illustration (Fig. 1), with its ample provision for additional units, is a proof that such a short-sighted policy has not been followed at Dortmund. The steam plant consists of four engines of 600 H.P. each, of the horizontal, compound type, which run at 90 revs. per min. The two engines on the side next the boiler house are direct-coupled to three phase generators, while the two engines on the side nearest the battery room drive the continuous-current dynamos. When working at 500 I.H.P. they have a steam consumption of 14·3lb. per horse-power hour. The speed may be varied directly from the switch-

Digitized by Google

board by means of a motor acting on the governor of the engine, in addition to the usual methods.

The continuous current dynamos are of the twin type, the armatures being supported in the middle of the shaft between the high-pressure and low-pressure cylinders. The field magnet of each dynamo has 30 poles, and the two armatures are entirely distinct from each other electrically. They are built by the Elektricitäts A.G., Frankfort, formerly Lahmeyer and Co. Each half of the twin machine has a capacity of 200 kw., with a voltage that can be varied from 220 to 370 volts. Each half can be used quite independently, or the two halves may be coupled in parallel to feed the outers of the 3-wire system, or to charge the batteries. When the electric trams are supplied by the Municipality the two armatures can be coupled in series, to furnish a pressure of 440 to 740 volts. Such a type of machine is of somewhat unusual construction, but it seems to overcome the difficulty of using the same plant for electric traction or lighting. In England the problem has been solved in another way, as we have arrived at 500 volts distribution on a 3-wire system, but in Germany anything like this pressure is extremely rare. The mechanical construction of the machine makes it a simple matter to examine the armature at any time. The field magnets can be very easily shifted apart along the shaft, and thus the necessity of lifting any heavy weight is avoided. The machines give 92·5 per cent. efficiency at full load, with 260 volts pressure, and 90 per cent. with 370 volts pressure. The three-phase generators have a capacity of 400 kw. at 2,600 volts, with a periodicity of 50. The fields are excited from the continuous current 'bus bars; the machines have an

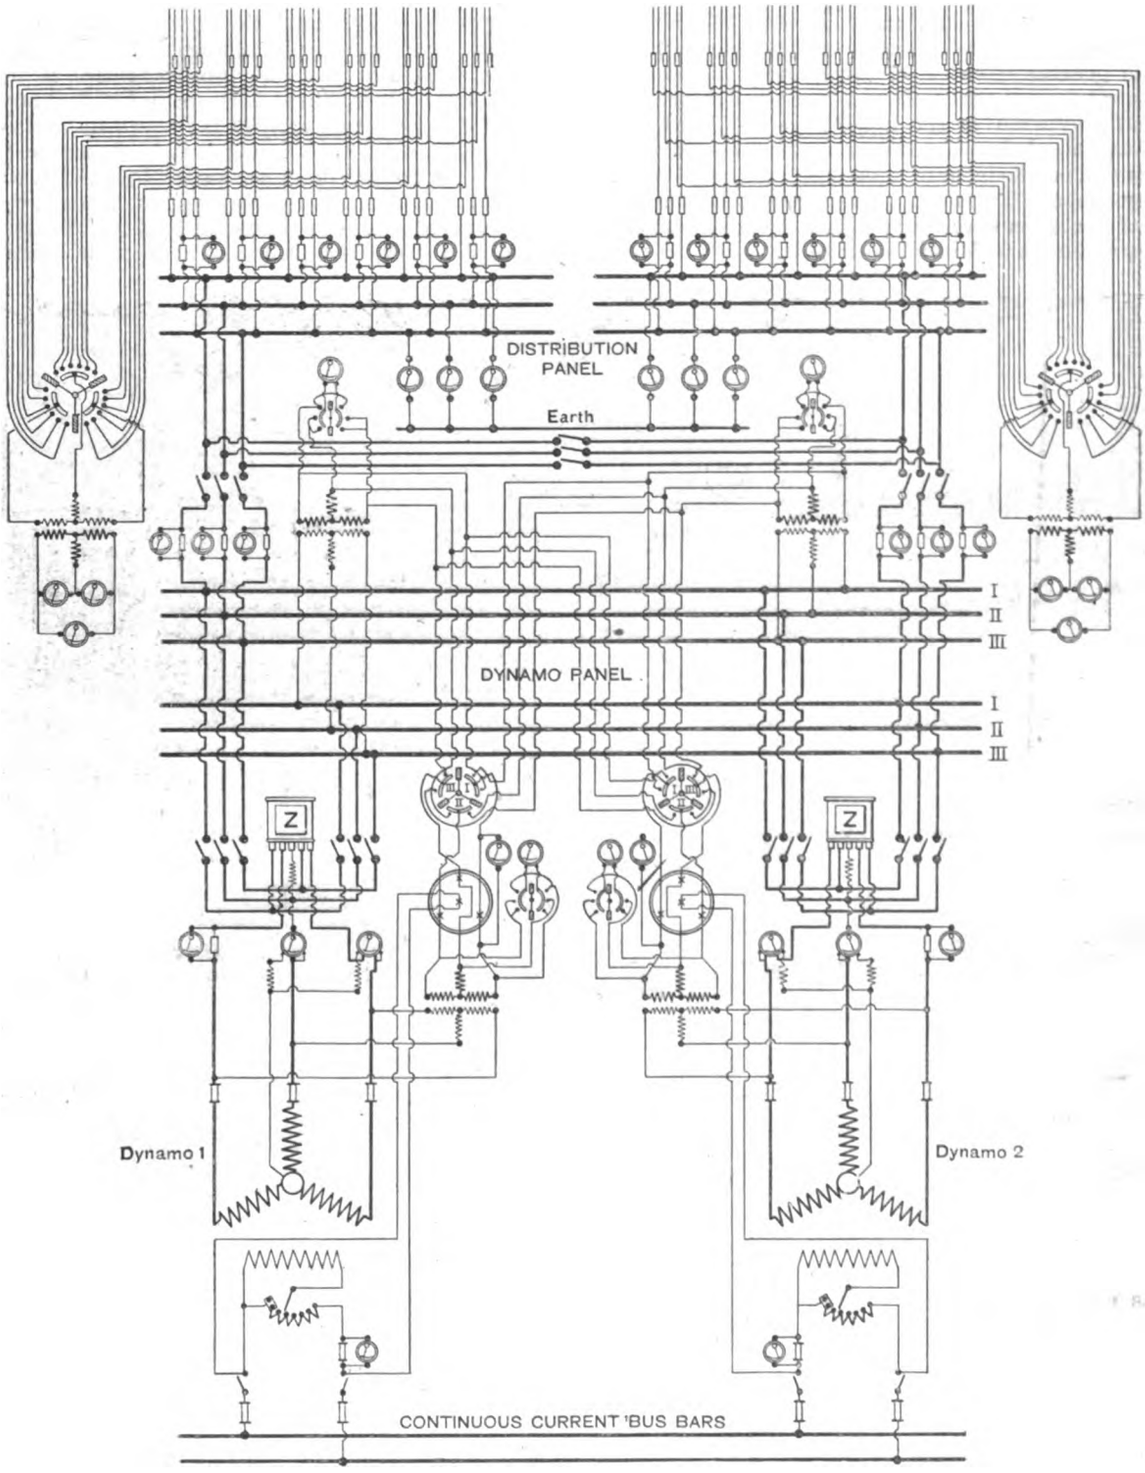

FIG. 3.—DIAGRAM OF CONNECTIONS ON THE THREE-PHASE SWITCHBOARD.

Digitized by Google

efficiency of 93 per cent. at full load and 88 per cent. at half-load.

The steam generating plant has no very striking peculiarities. The general arrangement is illustrated in Fig. 2. The boilers are of the water-tube type, working at 170lb. per square inch, and are fitted with superheaters. There is an ample firing space between the two batteries of boilers, and there is a separate shaft for each battery. When working at 140lb. pressure and 27°F., superheating and burning good steam coal, they have an efficiency of 70 per cent. The live steam piping is arranged on the usual ring main system, and is mounted on rollers to allow of expansion. An exhaust pipe of 3ft. diameter, laid under ground, leads from the engines to a central condenser. This central condenser has a capacity of 33,500lb. of steam per hour. There is a cooling tower, 84ft. in height, for the condensing water. This appears to be very efficient, as, when working with 83 per cent. vacuum, the amount of cooling water required is just equal to that of the steam condensed, which then possesses a temperature of about 140°F. The switchboard at the central station is divided into two parts, one for continuous current and one for three-phase, each being erected on the side of the engine room next the corresponding machines. The three-phase currents are distributed directly to the various parts of the town from the main switchboard, the connections of which are shown in Fig. 8. The continuous-current board has connected to it only the leads for charging the sub-stations and the mains from the dynamos. Each section of the switchboard is divided into a dynamo panel and a distribution panel. The whole is constructed of polished marble.

The accumulator sub-stations play an important part in the distribution scheme. These are three in number, one forming a part of the main-station building, and the two others being distant about 2,000 yards and 1,800 yards respectively from the central station. There are 132 cells in each station, but provision is made for 140, so as to be able to allow for a greater drop in the feeders in the future. The capacity of sub station No. I. is 3,536 ampere hours, the maximum discharge current being 833 amperes, and the maximum charging current 720. The two other sub-stations are of half this capacity, and the joint output of all three, when running at full load, is equal to 370 kw. The accumulators are of the system Gottfried Hagen of Cologne, and the capital cost per kilowatt is only £11. The efficiency of the batteries is 90 per cent. reckoning in ampere hours, and 80 per cent. in kilowatt hours. All the batteries are charged directly from the central station without the intervention of boosters or rotary transformers; space, however, is left for the installation of such apparatus should the necessity arise in the future. In each sub-station there is a connection to the three-phase network to permit of the installation of converters. As far as can be judged at the present moment, however, it will be a long time before such complicated methods of charging the cells will be required.

(To be concluded.)

THE ELECTRICAL EQUIPMENT OF SHIPS OF WAR.*

BY C. E. GROVE.

(Continued from page 14.)

Gun and Torpedo Work.—Electricity is an indispensable adjunct to the armament of a man-of-war, being invariably used for discharging torpedoes and for firing modern breech-loading guns of all sizes.

While all other circuits in the ship are twin-wired, gun and torpedo circuits are now universally single-wired. The following are the arrangements used in connection with Elswick equipments.

Torpedo-Firing Circuits.—Two batteries, one (A) of low, and one (B) of high resistance, are connected with their positive poles towards one another as shown in Fig. 21. The firing key and detector are fitted in the conning tower, from which the discharge of the torpedo is controlled. The torpedo is placed in the tube, the sluice-valve at the outer aperture of the tube being closed. The valve being closed, the firing circuit is open. The circuit is then "proved" by inserting a primer in the firing breech, when current flows from battery B, causing the sounder in the torpedo room to start buzzing, thus indicating that all is right. The primer is then removed and the sluice-valve opened, thus making contact at F, and completing the circuit through E, B, F, A, E, the two batteries being in opposition. The detector needle in the conning tower deflects to the left, indicating "valve open." The firing charge is inserted in the discharge chamber, the primer restored and the breech locked. Current from battery A through the high-resistance detector then flows in unison with that from battery B in the circuit E, A, F, P, E, reversing the deflection of the detector and indicating "ready." The officer in the conning tower at the proper movement depresses his

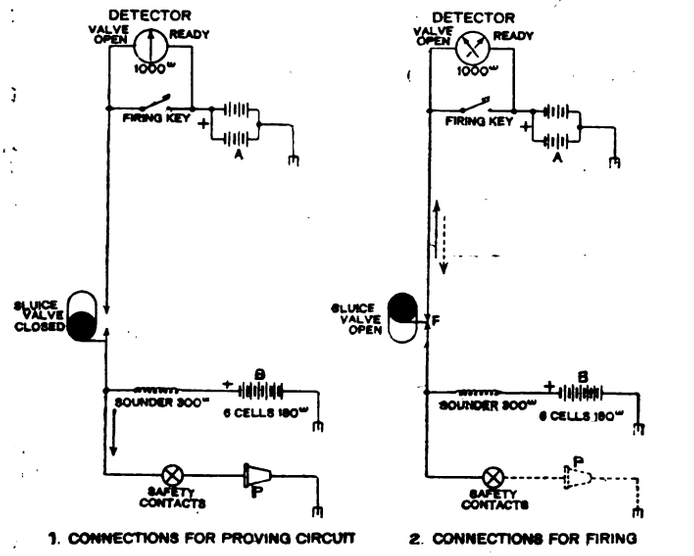

FIG. 21.—Torpedo Firing Circuit.

firing key, the two batteries send their full volume of current through the firing circuit in parallel, the fuse is ignited and the torpedo discharged.

Gun-Firing Circuits—A few years ago involved a formidable amount of wiring, as the circuits from all the barbette and casemate guns were looped into the conning tower, where the firing keys were situated. The practice now is to fire all guns on short local circuits, the batteries, switches, keys, &c., being carried on the gun mountings. Fig. 22 shows the connections for a pair of Armstrong barbette guns.

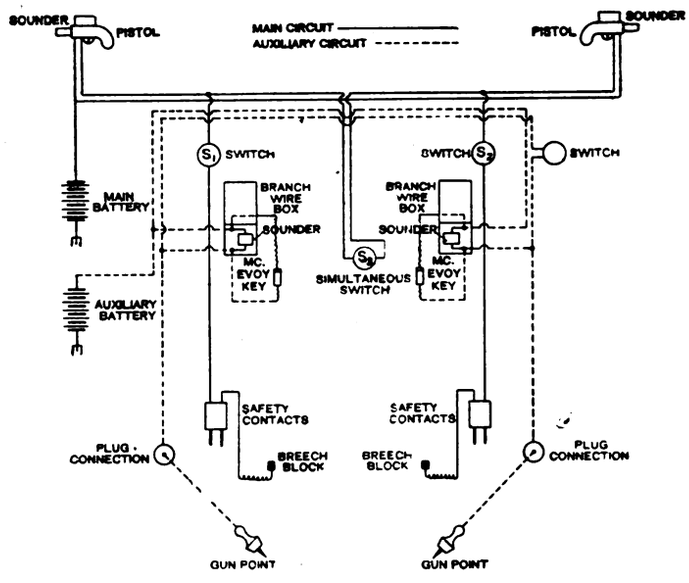

FIG. 22.—Gun Firing Circuit.

Following out the main (full line) circuit, it will be seen that if switches S_1, S_2 are closed and S_3 open, the left-hand pistol will fire the left gun and the right-hand pistol the right gun. If switch S_1 is open and S_2, S_3 closed, the left pistol fires the right gun; while if S_2 is open and S_1, S_3 closed, the right pistol fires the left gun. Finally, if all the switches are closed, both guns can be fired simultaneously from either side. An auxiliary circuit, shown in dotted lines, is fitted up as a stand-by to the main firing circuit. The latter is completed only when the gun is "right out"; he auxiliary circuit can fire with the gun in any position. The use

* Paper read before the Institution of Electrical Engineers, April 5th.

Digitized by Google

of the sounders will be evident, as they buzz all the time the circuit is made. Whereas the firing pistols are usually fixed at the firing platform, the McEvoy keys, connected by flexible connections, enable the gunner to fire from any position.

Range Finders.—These are sometimes electrical. That used by the United States Navy, invented by Lieut. Fiske, is based upon the Wheatstone bridge principle. Two telescopes (Fig. 23) are mounted so as to move over graduated arcs. In gear with the trains of movement are cylinders wound with resistance wire. When the telescopes are parallel, these resistances form

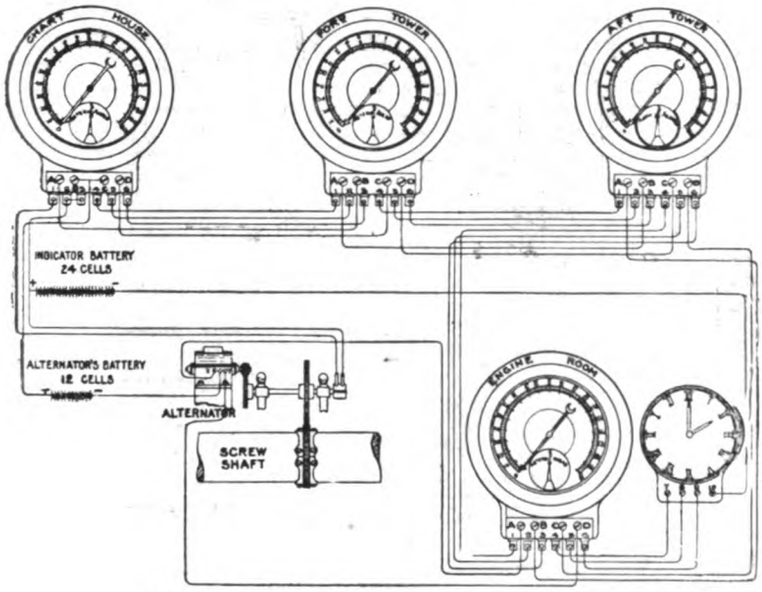

FIG. 28.—Molinari's Engine Revolution Indicators

balanced arms of a Wheatstone bridge. When the telescopes are trained so as to bring a distant object into the field of both simultaneously, the electrical balance is upset and current flows in the galvanometer to an extent depending upon the arc of training, which is a trigonometrical function of the distance of the object from the centre of the base line connecting the two telescopes. The base line should be as long as possible, whence one instrument is usually mounted on the forward bridge and one aft, the galvanometer being in the conning tower where the firing keys are placed. It is necessary to know this base line with great accuracy, or errors creep into the range. Further, three observers are necessary, who must be connected with each other by telephone. The method is a delicate one, and the difficulty of making the necessary adjustments, taken in conjunction with the difficulty of using the telephones during gun-firing, led, it is said, to the abandonment of the apparatus by the vessels engaged in the war with Spain, who found it easier to get the ranges by trial shots.

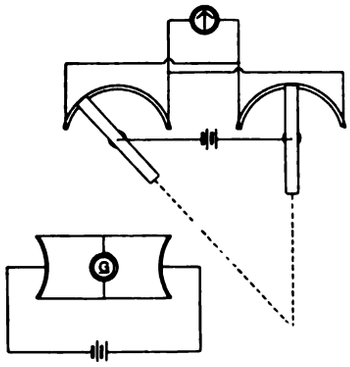

FIG. 23.—Diagram, "Fiske" Range Finder.

The range-finder used in the British Navy, and which has also been supplied to most foreign navies, is that of Barr and Stroud. It is designed for use by a single observer, but being a purely optical instrument does not call for detailed description here.* The ranges having been found, the next step is to transmit them to the various gun-stations. For this purpose Drs. Barr and Stroud have invented a system of *range and order telegraphs* for indicating simultaneously at any number of stations the range of a given object, together with information as to the guns which can be brought to bear upon it,

* Described in the *Proc. Inst. Mech. Eng.*, January, 1896

and orders as to firing. Figs. 24 and 25 show the general appearance of a set of such instruments supplied to the Japanese, who are adopting them generally. The British Admiralty have them on trial. As fitted in the ship, a single transmitter near the range-finder position gives the range upon a receiver in the conning tower.

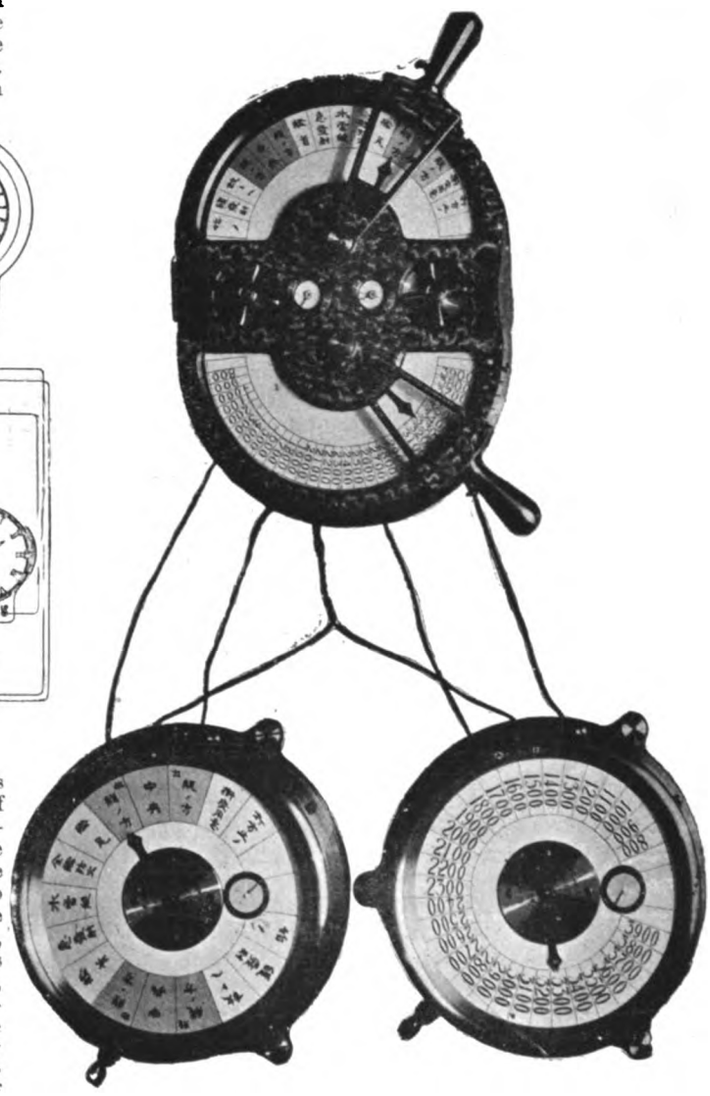

FIG. 24.—Barr and Stroud's Range and Order Telegraphs.

Adjacent to this receiver are two double transmitters for sending orders and ranges to the several casemates or to the barbettes, the receivers at which stations are grouped upon two main circuits, with bells which ring at every fresh signal received. The transmitters and receivers consist of clockwork mechanisms actuating, under electrical control, the movements of pointers over dial faces, on which figures representing ranges and symbols indicating orders are

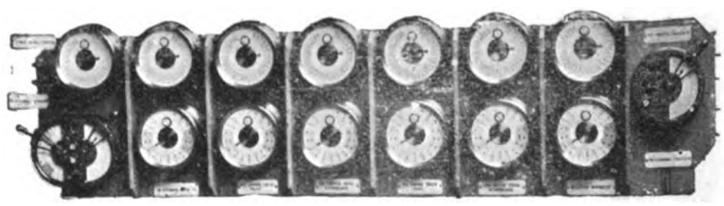

FIG. 25.—A Group of Range and Order Telegraph Instruments

inscribed. The transmitter has an outside handle moving about the centre of the instrument. To transmit an order, this handle is moved until its index pointer is over the required symbol. On moving, it puts current obtained by transformation from the lighting mains, into a small apparatus which starts an inside pointer following the outside index pointer. While this is moving, currents are being transmitted to the receivers at the distant stations, and the whole of the pointers are set in motion. They all stop together over the symbol under the index pointer of the transmitter. Being clockwork, the instruments have, of course, to be wound up periodically.

Navigation Instruments.

1. *Engine-room Telegraphs and Helm Indicators.*—An electric system of engine-room reply telegraphs worked out by Messrs. Richards and Evershed was fitted in H.M.S. "Howe" and "Narcissus" in 1893, to H.M.S. "Royal Sovereign" in 1896, and since then in other British war vessels. The indicating instruments have the appearance common to mechanical telegraphs, the dials being marked to show the usual direction orders, "Stop," "Slow," "Half," and "Full," "Ahead" or "Stern." The revolution of the indicating hand is effected by the combined operation of two electro-magnets (see Fig. 26) placed at right angles to one another, and producing between them a cross magnetic field, within which lies a magnet with which the indicating needle is geared. The position of the needle depends solely on the relative strength of these two field components, and this depends on the ratio of the current in the two coils. This ratio is controlled by the "transmitter," which consists of a multiple contact switch, through which the ordinary 80 volt electric light circuit is connected to a pair of ratio arms included in the same circuit as the coils of the indicator; the movement of the transmitter switches resistance out of one arm into the other, thus altering the relative value of the current strength in them, and controlling the movements of the indicator. An important detail is that the action does not depend on the absolute value of the currents in the indicator coils, but only upon their relative value, so that a constant voltage is unnecessary. A similar indicating instrument, graduated in degrees, is used for showing, at the several navigating

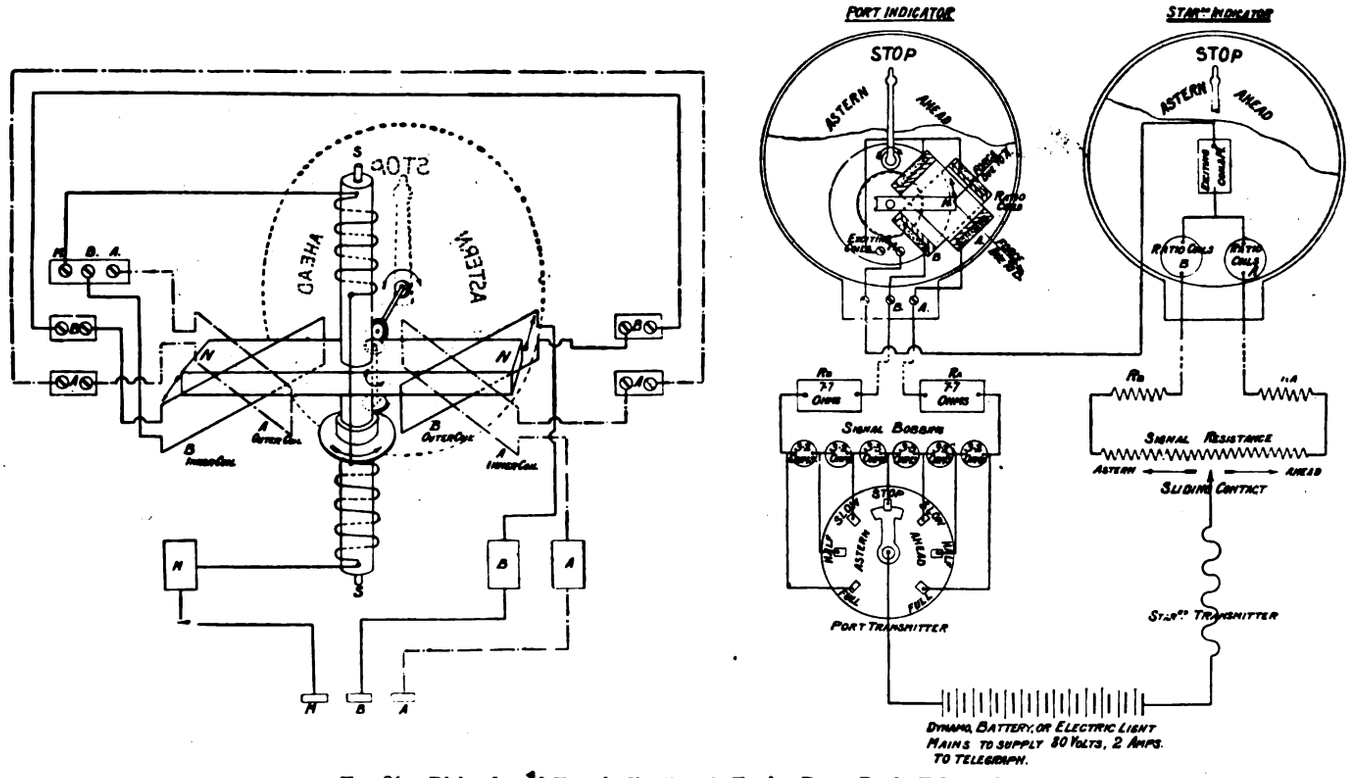

Fig. 26.—Richards and Evershed's Electric Engine Room Reply Telegraphs.

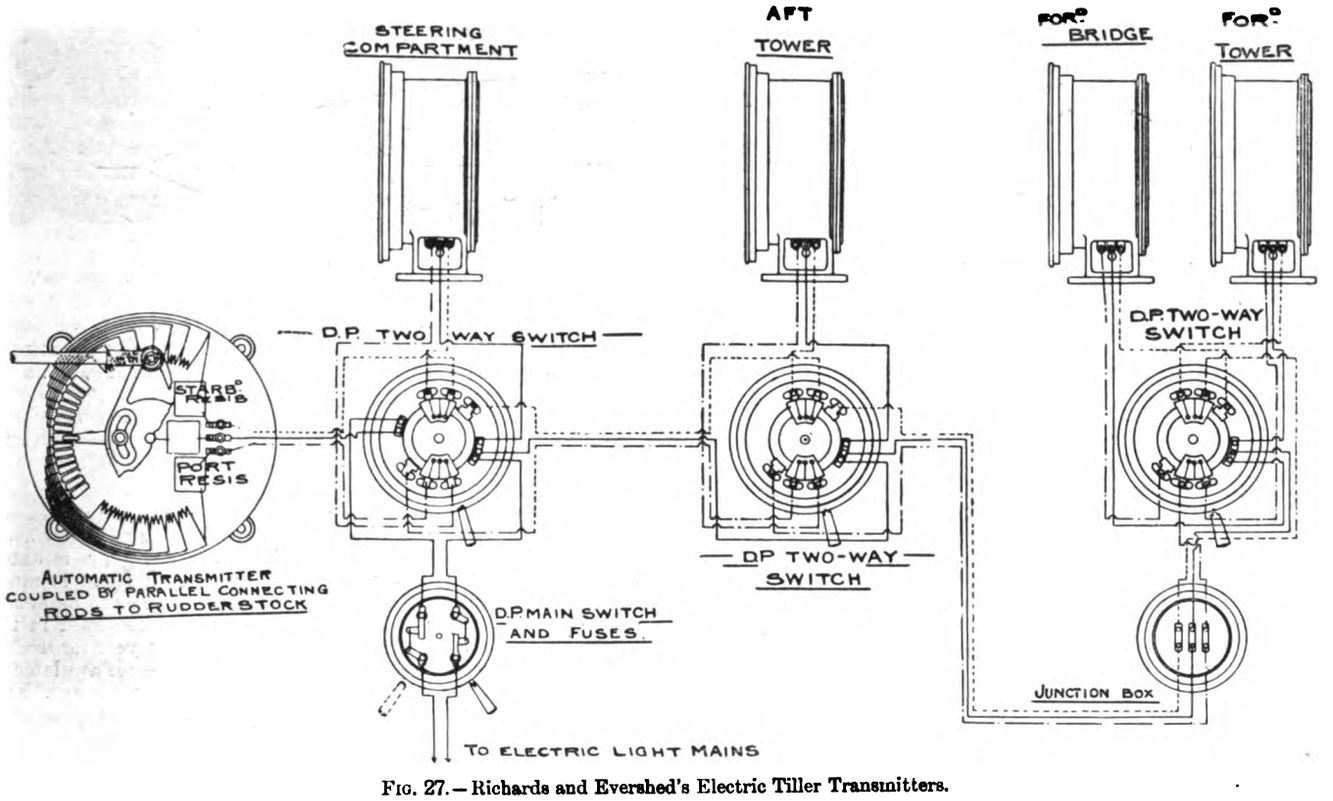

Fig. 27.—Richards and Evershed's Electric Tiller Transmitters.

Digitized by Google

stations, the angle made by the rudder, the transmitter switch in this case being automatically worked from the rudder crosshead (Fig. 27). By means of switches these telegraphs can be arranged to signal from any of several working positions—bridges and conning towers to wit. Transmitters send orders from any of these stations to a common receiving instrument in the steerage flat.

2. *Engine-room Indicators.*—A system for showing simultaneously in the bridge positions, conning towers, and other navigating stations, the revolutions of each set of engines, and for indicating in each engine-room the revolutions made not only by the set of engines in that room, but also by the set in the other room, is of great value. Such a system has been worked out by Signor P. Molinari, and has been adopted throughout the Italian navy, and is also used on warships of other countries. The indicating instruments (Fig. 28) are direct reading in revs. per min. They are clockwork instruments, kept in synchronism by a standard clock. This standard clock has a commutator within it which sends current for 20 sec. into the coils of an electromagnet in the indicating instruments, then breaks it for 4 sec, re establishes it for another 20 sec., and so on. While this current is on, the electromagnet holds a detent which allows an escapement motion to drive the indicating hand over the dial. Correcting currents sent by a revolving contact-maker driven by a friction wheel from the propeller shaft of the engine at the rate of three per revolution are received in separate electromagnet coils in the instrument, and while the main current, controlled by the standard clock, is disturbed for the 4-second interval mentioned, the correcting currents drive the indicating needle forward or pull it backward according as the average rate of revolution of the engines has been less or greater than that shown at the moment on the dial of the instrument. A galvanometer tell-tale for indicating "ahead" or "astern" is fixed in the bottom of the indicator case, and receives current from what is called by the inventor an "alternator," driven from the shaft in one direction or the other according as the ship is going ahead or astern. When no current passes at all the needle takes the mid position and indicates "stop."

(*b*) *Auxiliary Machinery.*—This general title covers a variety of machines whose functions fall into three principal classes.

(1) Those which co-operate with the main engines and boilers in the propulsion of the ship—*e.g.*, boiler feed-pumps, air and circulating pumps for condensers, fans for producing pressure in the stokeholds or furnace-blowing engines for working at "forced draught," steering engines, capstans for raising anchors, &c.

(2) Functions relating to the operation of the ship as a fighting machine—*e.g*, engines for moving turrets and for elevating and loading guns, hoists for raising ammunition, compressors for the supply of air under pressure to torpedoes, &c

(3) Domestic functions—*e.g.*, dynamos for lighting and fans for ventilating the ship, refrigerating plants for preserving food, pumping service for fire, bilge drainage, supplying fresh water and the like, hoisting machinery for lowering and picking up boats, &c.

In all, a first-class battleship carries nearly 100 sets of machinery, and a first-class cruiser 50 sets to 70 sets. Until a few years ago the whole of these auxiliaries were steam driven, with the exception of the gun-working machines, for which hydraulic power has long been preferred. By degrees electric driving has been applied to one and another, the most "advanced" examples being the United States battleship "Kearsage" just completed, which carries 55 motors and a generating plant of 350 kw. capacity. More has been written and said, both in Europe and America, within the last two or three years on this section of the subject than perhaps on any other, some persons roundly asserting that the time has come for driving all auxiliaries by electricity, while others are sceptical as to the desirability of employing electricity at all except for lighting and bells. Between these two extreme views, opinions exist of every intermediate grade

FIG. 29.—Location of Auxiliary Machinery on a Typical Battleship.

PART II.—MACHINERY AND POWER DISTRIBUTION.

The machinery of a modern ship of war consists of—

(*a*) *Main Propelling Machinery*, consisting of high-speed steam engines and high-pressure boilers. From the figures given by Sir William White at the 1899 meeting of the British Association at Dover as to the output and efficiency of this class of machinery for a given weight, and from calculations made by Mr. Alexander Siemens as to the weight of accumulators required to perform the same work, there is no difficulty in concluding that electricity will have no place for many a long day in the propulsion of large ships.*

Electricity as a motive power is now so commonly used on land that the charge against naval administrations in general, and the British Admiralty in particular, that they do not sufficiently avail themselves of this new mode of transmitting energy, is repeated with monotonous regularity by writers on the subject. It must, however, be remembered that it takes about three years to build and equip a large warship; if any novelty has been introduced in the design of the ship, it is not unreasonable to allow a year for trial of the novelty at sea, whence it follows that the experience available to naval designers to-day is that of the methods of four years ago. Now in electrical development four years is a long time, and thus it is evident that, judged by the standards of present-day land practice, naval designers would appear to be several years more backward than they really are.

The conditions under which auxiliary machinery works on board a warship are of a very special kind, requiring motors of special design to meet them successfully. Thus, a glance at diagram No. 29

* "With modern twin-screw engines and high steam pressure each ton weight produced from 6 H.P. to 7 H.P."—Sir William White, *loc. cit.*, *Engineering*, LXVIII. 341.

"A 6,000-ton ship propelled by 8,000 I.H.P. will take about 150 hours to cross the ocean, equal to 1,200,000 H.P. hours. Fairly efficient accumulators give about 10 watt hours per 1lb. of their weight, so that a horse-power hour can be obtained for 75lb. of accumulators. The ship in question would therefore have to load about 40,000 tons of accumulators for the trip across the Atlantic."—A. Siemens, *loc. cit.*, *Journal Soc. Arts*, XLVII. 820.

In other words, for 150 hours steaming 1 H.P. is produced from five tons of accumulators; hence, neglecting weight of electric motors and accessories, electric propulsion is inferior to steam propulsion on the score of weight in the ratio of at least 1:30.—AUTHOR.

Digitized by Google

shows that auxiliary machines are located all over the ship. Boat hoists and ash hoists are located on the upper and boat decks, exposed to all conditions of sea and weather. Motors in barbettes and turrets, fans in ventilating trunks, and (sometimes) capstan engines are liable to be drenched with water by seas shipped, or at least to suffer from the effects of spray; the machines on the upper decks get covered with grit when coaling, while machines working in machinery compartments below decks have to endure high temperatures for prolonged periods. All, wherever situated, have to be able to withstand rough usage, and are liable to be left idle for long periods when the ship is out of commission. The mention of these difficulties suggests that, with very few exceptions, electric motors used on board ship should be of enclosed watertight and dust-tight type, of extra strong mechanical construction to stand overloading, and arranged with long bearings and good automatic lubrication, so as to run for long periods with no attention at all; they should also be designed to work sparklessly with constant lead for all loads, so that the brushes are fixed; and moreover, the brush gear must be so designed that the brushes do not jump off the commutator if the machine is exposed to external vibration; the motors should run for normal periods with moderate temperature rise (the rise permissible depends on what is called the "normal period" of running, and will be different in such cases, for example, as electric ventilating fans, which ought to be able to run for two or three weeks on end, and capstan motors or boat-hoist motors, which in normal circumstances would work less than an hour at a time). The switchgear should be of massive construction, and should be an engineering apparatus, as substantial as a stop valve or a starting lever.

It cannot be said that all these requirements could have been met by the general run of electric motors produced four or five years ago, but they can all be met to-day. Cases, unfortunately, have occurred in which motors fulfilling none of the above conditions have been put on board ship. The cheap stock motor, suitable only for dry situations on land with good foundations, and requiring careful attention, has been installed and sent to sea. When, as is inevitable, such motors fail, the report sent in is less likely to be to the effect that "this particular motor is unsuitable" as that "electricity is not adapted to this class of work."

The modern traction type of motor best meets, on the whole, the requirements laid down as necessary for ship work, and the conditions under which it actually works on land are as bad, if not worse; yet the accumulating experience of the world that such motors will endure the very roughest usage, makes it unnecessary to argue further that enclosed motors can be built, of moderate weight and cost in relation to output, that will leave nothing to be desired on the ground of reliability. Reliability being the first consideration, the next in importance is simplicity in operation, combined with ease of inspection and repair. An electro-motor is a simpler machine to operate than a steam or hydraulic engine. It has fewer working parts requiring attention. Indeed, if only attention is given to supplying the bearings with oil and to cleaning the commutators periodically, there is nothing else for an attendant to do. Also a motor is cleaner in operation; it is not necessary to drain out a pipe full of water before it will start, and not only is the mess due to the absence of drainage water saved, but there is the advantage that the motor can be started instantly.

Cables for motors may, in like manner, be held to be a simpler means of transmission than steam or hydraulic pipes; they are more easily led about, weigh less, and take up less room than pipes capable of conveying an equivalent power, and they interfere less with the tructure and disposition of space in the ship. It has been objected against them that faults in cables are not so easily found as in the case of steam pipes, but if the cables are originally watertight, and are led about the ship from point-to-point junction or fuse boxes, it is not difficult to isolate the sections one at a time and locate the fault rapidly. If a fault exists, when it is found it can be repaired much more expeditiously than a leaky joint or other fault in pipes can be, especially steam pipes, which have to be allowed a long time to get cool before they can be handled. Further, if it is not convenient to repair a cable fault immediately, a temporary length of cable, not necessarily of the same size, can be run in and the faulty section disconnected. This cannot be done with pipe systems of distribution.

American writers point out two other disadvantages attending the use of steam-pipe system of distribution—(*a*) that the steam pipes heat the living spaces to an uncomfortable extent, (*b*) that pipes exposed to the effects of shot and shell are likely to be injured in action, and to lead to the demoralisation of the guns' crews. Neither of these considerations apply to modern British ships. Steam pipes do not pass through living quarters. Pipes to the steering and capstan engines pass through certain storerooms below the protective deck, but these are so chosen that the heat is unobjectionable. As regards the pipes to the deck hoists, which are exposed, they are usually led up the stokehold fidleys amidships, and are provided with valves below by which they can be shut off from the steam main in time of action.

(To be continued).

ON DISTANT ELECTRIC POWER TRANSMISSION.*

BY PROF. GEORGE FORBES, F.R.S.

Your President did me the honour to invite me to read a Paper on the subject of the distant electric transmission of power, to which I have devoted much attention during the last ten years. From the remarks he made at the time, it seemed to me that what he most desired was a description of the works of this character which have been established in different parts of the world, with the object of provoking a discussion on their various merits and defects by members of the Institution. I regret that to myself it seems undesirable that anyone should give to the Institution descriptions of works carried out elsewhere if he has not an intimate personal practical knowledge of the works; but in view of the fact that the discussion of this Paper may bring out information from those who have actually had the handling of such works, I have yielded to the President's wish to a certain extent. The first part of the Paper is devoted to the description of certain selected transmission plants, each one put up by a different contractor, and each one having some special point of interest. But I must freely confess that the only one of these of which I have that intimate practical knowledge which enables one to judge on the merits or defects of a scheme is the plant at Niagara Falls, the plans for which were prepared by me in 1890 and carried out between that date and 1895, and the actual working of which I have thoroughly investigated up to the summer of 1899, by a study of the journals, log-books, and complaints from consumers about faulty supply. Concerning the other installations, I have had to make use of the printed descriptions appearing in technical and other journals, which are always liable to mislead, especially as to the satisfactory nature of the supposed uninterrupted supply of power.

The second part of the Paper deals with some of the problems that face the consulting engineer in his attempts to introduce the highest economy, especially in the transmission lines, as this is the most important part when the distances are great. To these sections of the Paper some words have been added to give a general view of the methods in use by different contractors. Hitherto manufacturers and contractors in this country, having few great water powers in Great Britain, have neglected to attempt the supply of suitable machinery for other parts of the world, and run a risk of being passed over entirely in the future as they have been in the past, when tenders for the electric utilisation of water powers are asked for; it is perhaps wrong to say that they have been overlooked, and more just to say that they have refused to undertake such work. I venture to put forward the opinion that this is unwise, and I trust that the immediate progress that we expect in the transmission of power generated in the neighbourhood of coal-pits, will lead the manufacturers of this country to appreciate the large field that is opened to them abroad for the utilisation of water power.

If this be done I believe that British manufacturers may work upon new and independent lines, and that they will have a large outlet in our colonies and other parts of the world; because, out of numerous tenders that have been submitted to me for the transmission of power from waterfalls, none of the foreign firms who have tendered seem to me to have started on the best lines for making such a work successful and absolutely free from interruptions.

If our manufacturers, owing no doubt partly to the fact that their hands are full, have been unwilling to undertake these great works, while foreign firms have been making a splendid start, it must be allowed that the want of progress in our colonies is also largely due to the timidity of our financial men. It is not in this country that you would have found men with the boldness to risk their capital in transmitting and distributing electricity for power purposes, at a date (1890) when there was only one example of such transmission and distribution—viz., in a small village near the frontier of France and Switzerland. Nor would confidence have been placed by them in an electric transmission by means of alternating current, at a date when there was not a single alternating-current motor in commercial use, nor in the advantages of lower frequency than any which had been thought of up to that date (1893), when nine-tenths of the members of this Institution who rose to discuss the question condemned a frequency of 25 periods per second as impossible and extravagant.† Our capitalists are too apt to say that such things are too experimental, when any step is taken to improve methods. Yet the capitalists in America who undertook to utilise the Niagara Falls did all these things—they made a commercial and engineering success of their works, and have been imitated in their methods all over the world.‡

* Paper read before the Institution of Electrical Engineers, April 26.

† The unqualified success of the low frequency of Niagara Falls has now, however, converted even former opponents, and this Institution passed a recommendation last year that a frequency of 25 should be a standard for power transmission.

‡ The only financial group who ever in this country showed such boldness in electric matters was the band of men who realised that Ferranti's brilliant views were right, and who started the London Electric Supply Corporation.

Digitized by Google

Attention must now be drawn to a few of the most interesting cases of using electricity for developing the power of waterfalls.

1. Of the various plants for transmitting electrical power from waterfalls, one which derives its chief interest from the greater distance to which the energy is transported, is in South California at San Bernandino and Los Angelos, carried out by the General Electric Co., U.S.A. The water is taken from the streams in the San Bernandino Mountains, and it is carried in canals and tunnels for about 2¼ miles. It develops power under the head of over 700ft., three-phase electric currents are there generated and raised by transformers to a pressure of 33,000 volts, and the current is transmitted over a distance of 80 miles to Los Angelos; 80 per cent. of the water conduit is in tunnel, and of the rest part is open masonry canal and the remainder timber flumes. There are 18 tunnels whose total length is 11,555ft., the longest being 2,074ft. There are 2,662ft. of wooden flumes, 167ft. of open masonry canal, 121ft. for a sand box, and 57ft. of reservoir and forebay at the head of the penstock. The water is taken from a point 3,422ft. above sea level, the power house being at a level of 2,670ft.; the slope of the canal is 9·5ft per mile, leaving an available head of 728ft. at the power house. The streams used are the Santa Anna River and the Bear Creek.

The best description of the civil engineering works is given in the *Engineering News*, New York, March 9, 1899: Pelton wheels are used, with a nozzle 3⅜in. in diameter; the wheels are 82in. in diameter; the regulation is obtained by deflecting the nozzle from its most effective position as the load falls off: four such wheels and generators are in place; the generators deliver current in three phases, and the revolving wheels carry 20 poles, the armature being external. Each generator delivers 1,000 H.P., running at 300 revs. and giving 750 volts. There are 12 transformers, in banks of three, on foundations of steel beams and concrete, 30in. above the floor for the purpose of cooling by a forced air draught. Each transformer raises the pressure to 19,000 volts, making 33,000 volts between wires on the three-phase circuit, the star connection being used; three eighths of an ounce pressure is used, with blowers 280in. diameter, each requiring 3 H.P. There are two three-wire circuits of No. 1 (B. and S.) copper wire, and the insulators are placed on the posts at the angles of an equilateral triangle. These insulators, over 6in. diameter, are bell-shaped, of glazed porcelain, and are bolted to the cross-arm. There are 44 posts to the mile of white cedar, from 35ft. to 65ft. high, with 8in. tops. At Pesadena the voltage is reduced by oil-cooled transformers to 2,200 volts, and the current is used to work a synchronous motor which drives a direct-current generator of 525 kw. At Los Angelos there are six 250 kw. transformers reducing the electric pressure to 2,200 volts, and four synchronous motors which drive generators for lighting with continuous current. The information which would be most useful as to the results of working this plant would be about the continuity of working and freedom from interruptions. Such information cannot be obtained accurately except by a prolonged stay at the spot, examination of journals, &c. I am unable to assist in this.

II. The Snoqualmie Falls* have been developed for transmitting power to Seattle and Tacoma, by the Westinghouse Co., U.S.A. The features of greatest interest in this case are the use of the high electric pressure of 30,000 volts and the use of aluminium for the conductor on the long transmission line. It is impossible for any one to know what success has attended these novelties, unless he were to examine not only the plant but the log-book and correspondence. Continuity of performance is of primary importance, but we cannot tell from published accounts whether this has been attained in the present plant with 30,000 volts. Also we have not any means of knowing what success has attended the use of aluminium wire. In the development of the Snoqualmie Falls a vertical shaft has been dug 260ft. deep, 10ft. by 25ft., and the tail-race tunnel is 200ft. A 7ft. 6in. steel penstock is in place, and there is room for another. The underground chamber for machinery is 200ft. long, 40ft. wide, and 30ft. high. The penstock is connected at the bottom to a steel receiver 10ft. diameter, 1in. thick, and 80ft. long horizontally, besides 60ft. length of pipe 7ft. 6in. diameter.

There are four 1,500 kw. three-phase alternators at a frequency of 45 cycles, and at 1,000 volts. The armature rotates, and is 8ft. diameter, and weighs over 10 tons. Laminated poles are cast into the field frames. Transformers of 500 kw. with oil insulation are used. Mesh connection (or Δ) for the three phases is used both in primary and secondary. As to the high-pressure transmission line of 30 miles, it is said that 33 tons of aluminium are used for going to Seattle and 34 tons for going to Tacoma, and that each route has two separate three-phase circuits with 30in. between wires, that the average span to Seattle is 110ft. and to Tacoma 150ft., that Nos. 1 and 2 B.S. gauge and McIntyre joints are used. There is some discrepancy between the weights of wire used and the power that is said to be transmitted.

The whole of the information here given is taken from technical journals. On this line the electric pressure has sometimes been raised to 40,000 volts, when the phenomena of brush discharge acquire considerable importance. This led Mr. Scott, of Pittsburg, to his interesting experiments on this subject, published by the American Institute of Electrical Engineers.

III. The Paderno development of the* Adda River for supplying electric energy to supplement that in use at Milan, a distance of 33 kilometres, derives its chief special interest electrically from the fact that the energy is generated direct in the alternator at the comparatively high electric pressure of 13,500 volts, the plant having been designed and constructed by Messrs. Brown, Boveri and Co. The only other plant in the world which can be compared in this feature with Paderno is the transmission by the General Electric Co., U.S.A., from Mechanicsville to Schenectady, where both generator and motor are used at 10,000 volts without the intervention of any transformer.

It would be interesting to discuss the hydraulic part of the work at Paderno, but it is advisable under present conditions to confine remarks as far as possible to some of the electric details. Under the former head it may be said that the minimum flow of the river is taken at 45 tons per second. The dam is 150 metres long. The canal has a slope of 2 per cent., giving a velocity of 2·70 metres a second when the flow is the maximum allowed for. There are three tunnels, whose total length is 1,686 metres. The open canal is 582 metres. The total fall varies from 28·82 metres to 24·92 metres. The total head available is constantly 22·85 metres, and the suction varies from 6 metres to 2 metres, giving a total power of 13,000 B.H.P. The type of turbines is horizontal axis, double turbine to balance pressures, radial intake and axial outlet. Each double turbine developes 2,160 B H.P. at 180 revolutions per minute. A safety valve is provided, but is not required, as it was found, when closing the outlet of a fully loaded turbine in two seconds, that the pressure rose only 9 or 10 metres without using the valve.

The dynamos are of the well-known Brown construction. Each is of 2,160 H.P. at 180 revolutions, and developes three-phase currents. The armature is fixed and external to the revolving field, which carries 28 poles of steel with laminated horns. The poles are wound with copper strip edge-on. The diameter of the revolving field is 4·1 metres, and that of the whole machine is 5·14 metres. The exciter is in line with the alternator. The frequency is 42 cycles per second. The normal pressure is 13,500 volts at the terminals, and the current should be 64·5 amperes per phase with an induction factor of 1, or 79 amperes with 37deg. of lag. The efficiency in the former case is 95·1 per cent., in the latter 93·4 per cent. The maximum rise of temperature is 280°C. The machines were deliberately tested at 20,000 to 21,000 volts, and it is said that accidentally they were caused to generate current at 30,000 volts without injury.

The line consists of three independent three-wire circuits on two lines of posts 2 metres apart, the distance between any two wires of one circuit being 0·6 metre. The mean distance between the posts of one line is 60 metres. The distance of the high-tension transmission is 32,500 metres. The wires are of copper, 9mm. in diameter, the ohmic loss is 8·1 per cent. and the total loss is 11·7 per cent. for a lag of 37deg. A lag of 45deg. has been observed with a line on short circuit. Wurtz lightning arresters are used at both ends of the line on two of the circuits, and Siemens and Halske horns on the other. At Milan the pressure is reduced by Ganz transformers of 350 kw., and transmission gives place to distribution. The above statements of facts are on the authority of E. Vannotti, and were published by *Le Génie Civil*, Paris.

IV. The Rheinfelden plant† is here mentioned to allow of discussion on it, and because it is the most successful development of a low fall on the general lines of the Niagara undertaking. It resembles Niagara in using a vertical shaft for each turbine and dynamo. It differs from Niagara in having four different types of dynamos, some giving continuous, and others alternating, current. The turbines are by Escher Wyss, the dynamos by Oerlikon, and the Allgemeine Elektricitäts Gesellschaft. The hydraulic works are a model of good work, which I constantly kept before me when planning the work to be undertaken on the Nile Cataracts for the Egyptian Government.

If I were attempting here to give full descriptions, I would devote much space to this excellent installation. Many members of this institution have, however, inspected the plant, and every engineer who wishes to master this branch of our profession is obliged to read the most admirable description published at Berlin (*Die Kraftübertragungs-Werke Rheinfelden*).

V. In a Paper dealing with transmission schemes which have been carried out, the Genoa continuous-current plant deserves great attention. Here water power is available. The turbines are connected by insulating Raffard couplings to insulated dynamos, which are electrically connected in series. Thus 6,000 to 8,000 volts are delivered at Genoa to work insulated motors, also put in series so as to attain this high electric pressure. In a scheme purely for transmission, and not for distribution, this method of using continuous currents has a great deal of merit, and I believe that we shall all

Digitized by Google

agree that we owe a debt of gratitude to M. Thury for the way in which he has worked out the method at Genoa and elsewhere. A full account of this work has been published, and deserves the closest attention. I could mention cases which have come under my own notice where this system with continuous currents would give better results than the Niagara system with alternating currents.

VI. Having satisfied your President's wish and put forward as a basis of discussion some of the plants in different parts of the world, with the actual working of which I have no practical experience, it is a pleasure now to turn to the work of the Niagara Falls Power Co, concerning the working of which I may be able to supply useful information.

I do not propose here to give a full account of the machinery which we have made use of. It has been well described in the *American Electrician* for January, 1900.* It will be better to pass lightly over this part, and devote more attention to the lessons to be learnt from the five years of working. This plant derives its chief interest from the following facts: (1) It was the first place except Oyonnax where a scheme was started on for generating electricity at a waterfall, transmitting it to a distance, and distributing it to consumers for power; (2) It was and is the largest project of the kind; (3) It was the first case of using the alternating current for power commercially. (4) It was the first case in practice where the commutator for continuous currents was placed at the distant end of the transmission line; (5) It was the first plant to adopt low frequency; (6) All the generators are of the same size and pattern; (7) The Niagara system in its general features has been adopted in almost every subsequent electrical development of water power. The principal feature of the dynamos is that the shaft is vertical, and that the revolving field has its poles external to the armature. In the original drawings and specification issued to manufacturers a circulation of fluid for cooling the armature was provided; the poles were wound with copper strip and mica insulation, and not with wire; and there were no bolts on the outside ring to create undue air friction. I allowed the first three dynamos to be built without these features, but the last seven have had them reintroduced.

The transformers at the power house are the first ever made of great size, and also the first made with great attention paid to cooling by air-blast or oil. Those by the General Electric Co. are 1,250 H.P. Those by the Westinghouse Co. are 2,500 H.P. For the factories within half-a-mile a subway is used, which I built of concrete. For the new Carbide works a "Camp" conduit, like our "Doulton" conduit is used with 10,000 volts. For the Buffalo transmission bare overhead wire cables are used.

The Aluminium Co. had great trouble at first with the rotary transformers used for commutating the current. These were, I believe, the first machines of this class ever ordered for commercial use. The Mathiessen Alkali Works have 11 such machines, with one induction motor for starting the middle one. The others are started from this by temporary belts. They have no hunting, no sparking, and no grooves on the commutators. Hunting is prevented by a modification of the Leblanc cage on the poles. Each machine has six poles, and sparking is prevented by connecting together metallically all the commutator-bars which are in the same phase. To prevent grooving of commutators the shaft is free to move axially, and motion is given to it by an electro-magnet and spring, the current for the electro-magnet being periodically interrupted by clockwork mechanism on the wall.

The Carborundum Co.'s plant is chiefly interesting for the adjustable transformers, which allow very large variations in the volts and current. These have often been described in technical journals. This service could not have been given had we adopted three-phase alternators, and the rotary transformers would not have succeeded but for our low frequency. In the new works of the Carbide Co., 10 Wagner transformers, each of 2,000 H.P., were being put in when I was last there. This plant is interesting from the fact that the serious short circuits frequently occurring in the electric furnace can be satisfactorily dealt with.

Passing over other matters concerning which a volume might be written, it will be well to say a few words about the transmission line to Buffalo. The chief peculiarity of the Buffalo transmission line is that three-phase currents are used, though generated in two phases. I very much preferred alternators of two phases as being more easily tested and attended to, and as giving a more useful machine. For the transmission to Buffalo I had no great preference for one over the other, but I found that we should be better served by yielding to the wishes of the contractors and putting in Mr. Scott's ingenious arrangement for changing from two-phase to three-phase. *Fig.* 1 shows the connections.

There were six bare cables on one cross-arm of the posts all the way from Niagara to Buffalo, but this arrangement is to be altered.

From Niagara to Terminal House, Buffalo, is 25 miles.
From Terminal House to Railway House is 2 miles.
From Terminal House to Lighting House is 4 miles.
From Terminal House to 3 Sub-stations is 4½ miles.

The full-load inductive E.M.F. is 15 per cent. of the whole. At some stations the current leads the E.M.F. instead of lagging. The Buffalo cables are three insulated lead-covered cables in a pipe, and the capacity of each is 0·55 m.f. per mile from copper to lead. The conductors on the transmission line are 0·6in. diameter, 18in. apart half the way, 36in. the rest. The posts are 75ft. apart. The top cross arms are 30ft. above ground. The posts are 8in. diameter at the top. They are not strong enough for the weight and are bent badly. Originally a barbed wire ran the whole distance over the conducting wires. After the snowstorm of Dec. 4, 1898, it was removed. It was grounded at every second post. Having looked carefully into the cause of every interruption of electric supply that has occurred in four years, I have to say that not a single electrical trouble has occurred that might not be prevented in any similar plant laid down in future.

In this brief reference to the work at Niagara Falls many features of considerable importance must be omitted; but I should like to draw attention to the ingenious automatic cut-outs with the introduction of which I had nothing to do, and which I am therefore free to praise, as they have been of the highest value in preventing interruptions of supply on the Buffalo transmission. The electro-magnetic arrangement, which comes into play when excessive current passes due to a short circuit, merely serves to start some clock mechanism which after a short period cuts out the line if the excessive current is still passing. On the Buffalo distribution these automatic cut-outs are set so as to act after one or two seconds; at the Buffalo end of the transmission line after three seconds, and at the Niagara end after four seconds. Thus a short in Buffalo cuts out the distributing lines, and no others. At the Terminal House, Buffalo, it cuts out the supply mains, but not the transmission line; and at Niagara, if a short last four seconds, the supply to the transmission line is cut out.

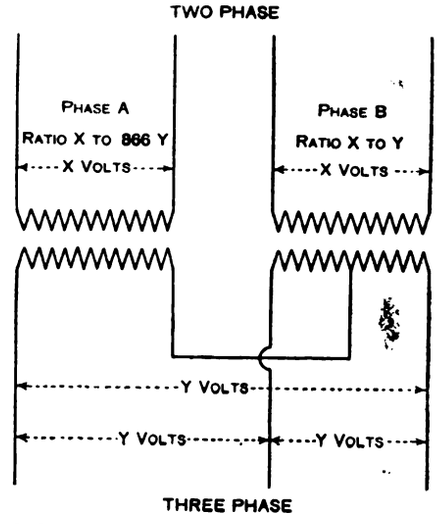

FIG. 1.—Sketch showing transformation from two phases to three phases.

Another ingenious appliance at Buffalo is a motor supplied by the three transmission cables, so balanced that the motor will not move except when the balance is destroyed by an earth or short circuit on the line, when its motion removes the defective line, or switches the whole load on to the other line.

There is a practical matter regarding the regulation of the turbines which deserves notice. At the period of my last inspection Buffalo was supplied by two dynamos. Now the first three turbines put down were regulated by a purely mechanical governor; the later ones by a more sensitive electrical governor. It is found in practice that the supply at Buffalo is most steady when the two turbines driving the dynamos are regulated, one by a sensitive, and the other by a coarser governor.

In conclusion of these remarks about the Niagara-Buffalo transmission it may be interesting to mention a few of the causes of interruption of the current. Some of the Italian workmen stole copper wire. They were put in prison. Whereupon their relatives short-circuited the wires. Boys threw chains over the transmission wires to watch the sparks until the detectives caught them. Short-circuits or earths have also been caused by fumes and carbon dust deposited on snow on the insulators, by fourth of July rockets, by sleet, by lightning, by careless workmen, by rats. Interruptions have occurred by overload on rotary transformers, by attendants using switches wrongly, by lightning arresters, by bad switches on consumers' premises, by accidental fire, by ice blocks on the canal headrace. Insulators are a temptation to the owners of revolvers, but this trouble has not existed at Niagara so much as in Switzerland. These are only extracts from the nearly complete list which I made out from four years' working.

(To be concluded.)

ELECTRICITY WORKS ACCOUNTS.

Brighton Municipal Electric Supply Works.

From our table summarising the accounts of the Brighton undertaking for 1899 it will be noticed that the excellent results of the preceding year have hardly been maintained either in respect of increase of business or in economy of working. In the latter sense the retrogression has been very slight, and has been due to extraordinary expenditure. The rise in the aggregate costs of 0·12d. per unit has brought them up to 1·8d.—a figure still most satisfactory, even in view of the large output and the increased load factor of 16·6 per cent. with which the undertaking was blessed last year. The fuel charge has diminished, and stands at what is a most reasonable figure for a town situated as Brighton is in respect to a coal field. If there are any items which seem a little high to us, they are those of wages and repairs and maintenance at the station, but management and property charges present practically the same satisfactory figure that they did in 1898.

The reduction in the tariff has had its due effect on the revenue, the total from all sources being 3·06d. per unit or 2·94d. for supply for lighting, public and private. Again, in view of Brighton's situation this is an excellent result, and will stimulate the progress of the undertaking in the matter of lamp connections, the increase in which last year fell to 19·7 per cent. The increase in the output was also not so great as in 1898 being only 21 per cent. Considering the order of the output in relation to the size of the town it is surprising to find the progress in lamp connections so well maintained as it is.

The load factor shows a gratifying increase from 15·4 per cent. in 1898 to 16·6 per cent. last year, the maximum demand on the mains (selling load) being 1,962 kw. in 1898 and 2,206 kw. in 1899, while the maximum load reached was 2,376 kw. in 1898 and 2,538 kw. last year.

In the original accounts, under the headings "Street lighting installations" and "Attending public lamps and repairs, including materials supplied," there are items for 1898 of £366 and £3,437, and for last year of £157 and £4,350 respectively. These charges in the expenditure are exactly balanced by similar figures in the revenue, in addition to the sums accruing from the charge per unit for supply for public lighting. We have allowed the amounts stated to vanish from both sides of the account, so that as our analysis stands the costs and revenue are directly comparable with concerns where the arc lighting would have been by private consumers. If the items had been included, the total revenue, instead of figuring at 3·43d. in 1898 and 3·06d. per unit in 1899, would have come out at 3·77d. and 3·39d., while the total costs, instead of being 1·68d. in 1898 and 1·80d. in 1899—as shown in our table—would have stood at 2·025d. and 2·14d. respectively.

We learn that items of unusual expenditure out of revenue were—alteration to buildings, £200; renewal of accumulators, £470. These, with the increased cost of labour, are chiefly accountable for the slight advance in the costs, and more particularly the two items which were referred to above as appearing high.

The Eastbourne Electric Light Co. (Ltd.)

Although we are again able to record material progress in the year's results of working of this undertaking, its position is still below what might reasonably have been expected of a concern of such long standing. Both the costs and the revenue continue to stand at figures above what they should be, even considering the disadvantageous situation of Eastbourne in respect of cheap fuel supply.

Last year the lamp connections were increased by 18·6 per cent., while the output reached 857,585 units sold, or about 16 per cent. above that of 1898. In view of the high price per unit, it is somewhat surprising that the business continues to increase at the rate it does.

The load factor here is above the average, in 1898 it was 11·3 per cent. and last year 11·8 per cent.

Among the costs, the "management and property charges" per unit are very moderate, but all the generating costs, except "repairs and maintenance at station," still stand at high values, although they have been reduced.

The sale of the undertaking was completed on Jan. 1, since which date the concern has been under municipal control.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

Aberdeen (Municipal)	Jan. 12, 1900	Kingston-on-Thames (Mun.)	April 21, 1899

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

u blished every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,

I, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to THE EDITOR.

All letters for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	YEAR	HALF-YEAR	QUARTER	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited. The well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. ELTON YOUNG, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. FISHER and J. C. H. DARBY. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. PHILLIPS. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. FISHER. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C RAPHAEL. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof J. A. EWING, M.A. New edition. Price 10s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 8d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DAVE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICE.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (950 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

PROSPECT AND RETROSPECT.

The country is on the eve of an industrial crisis. The moment is at hand when Parliament will have to decide whether the United Kingdom is, or is not, to be blessed with the advantages accruing from a widespread supply of really cheap electric power. In view of the industrial and social importance of cheap power, and taking into consideration the national character of the issue, we feel justified in describing the impending Parliamentary decision as one that constitutes a national crisis. At the present moment, some six bills relating to schemes of unusual magnitude for the supply of cheap electric power are entering the committee stage of their progress through the House of Commons, besides numerous other bills relating to electrical undertakings of various kinds, which are in different stages of progress. Parliament has already recognised, in the Joint Committee which made its report in 1898, the principle upon which depend the six schemes referred to—namely, that "where sufficient public advantage is shown, powers may be given for the supply of electrical energy over an area including districts of numerous local authorities, and involving plant of exceptional dimensions and high voltage." The Committee further thought "that undertakings of this character may properly be authorised on conditions differing in some respects from those imposed by and under the existing Acts." Since this enlightened report was made Parliament has seen fit to throw out more than one bill based upon that principle; and as yet it has never affirmed its adherence to the principle by the passage of any effective Act. Having regard to these Parliamentary precedents, and to the opposition which is being threatened by local authorities to the bills now before the House of Commons, it is of the utmost importance that publicity should be given to the real nature of the present issue before the Legislature.

Let us look backward, for a moment, to the early dawn of electrical supply. The social and industrial possibilities of electricity were then ungauged; imagination painted them in rosy colours and magnified them into gigantic dimensions. The passage of the Electric Lighting Acts, and the advent of public electric supply as regulated by those Acts, were to usher in a new era of social and industrial civilisation—an Age of Electricity, in which all the unhealthy conditions of the age of steam power and gas light were to disappear. Cheap electric power for every existing purpose, and for a host of imagined new purposes, was to lighten the labours of the working class, brighten the conditions of home life, increase the earning power of capital and

Digitized by Google

labour, and generally to introduce a millennium of material civilisation. Twelve years have passed since the passage of the Electric Lighting Act (1888), but where is the new civilisation? Where are the towns, the factories of which know no chimneys; the workshops of which are everywhere run by cleanly electric motors, in place of noisy and dangerous shafts and belting; the homes and retail shops and business houses of which have power "on tap" so cheaply that manual labour is materially lightened, and unhealthy gas and oil engines have been abolished for ever? Cities such as this certainly exist, but not under the Electric Lighting Acts; they are to be found only outside the United Kingdom, in places where it is possible to take advantage of the best conditions for supplying electrical energy, unhampered by unwisely restrictive legislation. Within the territory controlled by these Acts sufficient growth of the industry of electric supply has been effectively checked by the confinement of that industry within unnaturally small limits. The industry has never been permitted free expansion; cribbed, cabined, and confined within the narrow area controlled by some one municipal authority, it has been half-stifled and has never grown to full maturity. True, even within these limits, electricity has given considerable indication of its latent powers. It has everywhere proved itself the cheapest and altogether the best form of artificial illuminant; it has offered power to the small user on terms which many have been able advantageously to accept. But, nevertheless, it clearly has not accomplished the results which a more free scope and a wider and more comprehensive arena would have allowed. For, the one fact more unmistakably emphasised than any other by the past twelve years' experience of electric supply undertakings is, that in proportion to the magnitude and comprehensiveness of any system of electrical supply, so is the lowness of the price at which that supply can be made without financial loss. The soil wherein electricity supply most thrives is one in which its roots may strike out beneath a large area, rich in a great variety of nutriment. In plain language, really cheap electricity is impossible unless the area of supply is extensive, and comprises such a variety of consumers that the supply can be maintained constantly at approximately its full-load rate.

This is a fact of engineering; it has nothing to do with politics. Whether the reader be in favour of, or be opposed to, the political municipalisation of electrical undertakings, the great engineering principle stands firm: that in order to obtain the fullest advantages of electric supply, the area of supply must cover not merely one town or city, but many towns —whole counties, in fact; and within that area there must exist demands for current, not merely for lighting, but also for motor power and industrial purposes. Only in this way can the dream of an Age of Electricity have any prospect of being realised in this country. Succinctly, therefore, what is needed is that powers should be granted by Parliament for the construction of large systems of electrical supply, each covering extensive areas and including many towns and villages within its scope. This much definitely settled, the question arises: To whom should such powers be granted? If it is urged that they should be granted to the local authorities, within the meaning of the Electric Lighting Act (1888), our reply is that each separate local authority controls far too restricted an area. Concerted action on the part of all the local authorities within, say, any county is conceivable, though it is doubtful if it would receive Parliamentary sanction; but, be it observed, local authorities have shown no disposition whatever to combine on this large scale—they are engrossed with their own rights to erect petty local systems of supply. Again, it may be thought that the County Councils might take up the business of supplying electricity over their county districts; and doubtless it is open to any County Council to promote a bill to obtain such powers and privileges, but not one has yet done so. No, as usual it has been left to private enterprise to seek authority from Parliament to develop this new class of industry; and all that the local authorities have been content to do has been to present a solid front in opposition.

Amazement at this attitude of our local governing bodies, towards a matter of such vital importance to the nation, is intensified when we consider the weakling arguments which are advanced in defence of their position. It is alleged, for instance, that the new schemes, if put into operation, would supply electricity so much cheaper than the local authorities can supply it that the local works would no longer bring in any contribution for the relief of the rates. This is the cry of the man who says he will not work because he would then no longer receive parish relief. It is to prefer the muckrake of petty socialism to the golden crown of increased industrial prosperity. Let the rates take care of themselves, if so be every encouragement can be given to promote new industries and to increase those existing already! Another argument, equally fatuous and purblind, which is extensively advanced, is that the proposed schemes would create dangerous monopolies. They would create no monopoly of any description, dangerous or otherwise. On the contrary, it is especially provided that each local authority shall have precisely the same rights as hitherto to erect works of its own on its own area. Local authorities have a free option to purchase cheaply in bulk from the distribution company, or to generate expensively in their own sweet way; to their own ratepayers alone stand they responsible for their choice. Where is the monopoly in this? If any exist, it is merely the monopoly naturally acquired by the man who is willing to sell for a penny what no other mortal can make for twice or thrice the money. We repeat, there is no monopoly. Yet another so-called argument advanced in opposition is the outcry that it is monstrous for private companies to be allowed to break up public streets. The streets have to be broken up anyway, and we have yet to discover that a local authority ever does it with less inconvenience to the public than an electric supply company does. But the point of the argument ceases to exist, when we discover in the new schemes that all the alleged objectionable street-breaking is to be done, not by the supply company at all, but by the local authority. It is so laid down in the bills themselves. True, there is a wise provision that a local authority may, if it pleases, hand over this work and all the business of retail supply to the company; but there is absolutely no ground for the stump orator of any local authority to make such a clamour about the breaking-up of streets. Yet supine and indifferent ratepayers by the thousand are being lulled into unconsciousness of the true nature of the crisis by clap trap talk and inspired newspaper misstatements throughout the country. Local authorities have set their faces against the principle underlying these bills, and they are banded together to oppose it wherever it appears before Parliament. They are actuated purely by a selfish and narrow-minded determination to sacrifice every consideration of national welfare rather than that their own pet theories of socialism should be set at naught, or that their own little schemes for local electricity supply should be eclipsed by anything better adapted to the needs of the locality, and of the nation at large.

May the hollowness of the pretensions of these enemies of industrial and social progress be exposed in time to

Digitized by Google

prevent the mischief they are plotting. It is the duty of every member of the electrical profession to thwart them in every possible manner. Conversely, it will be to his eternal shame and disgrace, if any member of this profession should appear before the Committee of the House of Commons in order to give evidence against the principle involved in these projects. We hear that an eminent electrician—possibly more than one such—intends to give evidence against the bills. On a technical matter of detail it is possible, of course, that a consulting engineer might find reasonable ground for objecting to a portion of any individual scheme; but the nature of the objection should be most carefully explained to the Committee, and every electrical engineer who gives evidence should testify to the just claims of the schemes, each considered as a whole. Details of this character, moreover, need not destroy an entire scheme; they can be adjusted by the Committee without sacrificing the bill. Indeed, so entirely reasonable appear all the bills at present before Parliament that it should be an easy matter to get over any such technical objections that may arise. But even though one or two of the bills may unfortunately be thrown out, the passage of the remainder will be the signal for the inauguration of a new era in electricity supply, and one that will witness a widespread development of industrial and social electricity utilisation, compared with which the past twelve years of local electricity supply will be but as "a very little thing."

NINETEENTH-CENTURY CLOUDS OVER THE DYNAMICAL THEORY OF HEAT AND LIGHT.

The first Friday evening discourse after the Easter recess was delivered by Lord Kelvin, on the above subject, on Friday evening last at the Royal Institution. At the outset Lord Kelvin remarked that his subject was necessarily a sombre one. It dealt with the clouds which had hung over the dynamical theory of both heat and light ever since its inception, and which alone tended to obscure the great brilliancy and the perfect clearness of this theory. The theory was one, in that heat and light were both considered to be "modes of motion," subject to the same laws as those connecting the motion produced in matter by a force acting on it.

The first cloud to which he referred was that one which came into evidence with the undulatory theory of light, and was first dealt with by Fresnel in a letter to Arago, published in the *Ann. de Chimie u. Physik* (1818). It consists in the difficulty of conceiving how, if the ether be assumed to be an elastic solid, as demanded by the undulatory theory, the earth and other bodies can move so freely through it. Young thought that the ether may be considered as blowing through gross matter, like "the wind through a grove of trees." Further investigation enabled us to add, "much more so," and still in spite of this extraordinary mobility of the ether, and in spite also of the remarkably ingenious and delicate experiments of Michelson and Morley, in America, on the relation between ether and matter, leading to the result from which he (Lord Kelvin) saw no possibility of escape, *i.e.*, that there is no motion of the ether relative to matter, he persisted in his opinion that matter does *not* move freely through the ether.

The second great cloud over the dynamical theory lay in the Maxwell-Boltzmann doctrine of the partition of kinetic energy. This cloud was now 30 years old, and was not yet dissolved. Maxwell himself was not absolutely convinced of the truth of this doctrine, and in his address to the Chemical Society (1875) openly expressed some of his doubts. Lord Rayleigh also, so recently as January, 1900 (*Phil. Mag.*), sought "some escape from the destructive simplicity of the general conclusion relating to the partition of kinetic energy." The easiest escape was to reject the doctrine altogether, and to say that, in spite of its support by Maxwell, Boltzmann, Poincaré, Rayleigh, and by Watson and Burbury, the mathematics did not prove it.

The discrepancy between theory and experiment is most strongly marked in the case of the ratios of the specific heats of various gases, and illustrated in the following table:—

Substance.	Ratio of specific heats.	
	According to M.B. doctrine.	Found from expt.
Air	$1\frac{2}{7}=1{\cdot}2858$	1·406
H_2	,,	1·42
O_2	,,	1·41
Cl_2	,,	1·32
CO	,,	1·39
NO	,,	1·39
CO_2	$1\frac{1}{3}=1{\cdot}1667$	1·30
N_2O	,,	1·331
NH_3	$1\frac{1}{3}=1{\cdot}111$	1·311

An absolutely true doctrine, Lord Kelvin thought, was first proposed by Clausius, according to whom the relation between the specific heats is given by the formula

$$\frac{C_p - C_v}{C_p} = \frac{2}{3}\,\frac{\text{average translational energy}}{\text{whole energy of motion of centre of mass}}$$

He had recently been occupied with a very simple case, that of the motion of a particle in a plane, or, say, a ball on a billiard table. But instead of a rectangular billiard table, he would suppose a triangular one to be available. If the Maxwell-Boltzmann doctrine were true, then, after a large number of impacts, the average kinetic energy in any two perpendicular directions must be equal. Since January he had worked out about 1,000 cases, and he was able to say, as a result of those calculations, that the Maxwell-Boltzmann doctrine was not true. In two typical cases, after 100 impacts, the average kinetic energies in two perpendicular directions came out to be 56 and 44 in the first case, and 53 and 47 in the second case. He held, therefore, that the Maxwell-Boltzmann doctrine did not hold for this simple case, and therefore that it was absolutely disproved. In conclusion, Lord Kelvin brought forward some considerations respecting the structure of the atom and the ether, pointing out that the ether must be truly imponderable, and quite outside the law of universal gravitation.

A CENTURY OF CHEMISTRY AT THE ROYAL INSTITUTION.

LECTURE I.

At the Royal Institution, on Thursday, April 26, Prof. J. Dewar, F.R.S., delivered the first of a series of four lectures on "A Century of Chemistry at the Royal Institution." He began by referring to the centenary of the Institution, which had been celebrated last year, and suggested that these celebrations naturally raised a spirit of inquiry and criticism as to how much his own predecessors did, and how much they had suggested and contributed to chemical science of to-day. There existed considerable interest at the beginning of the century relative to the wonderful discovery of the voltaic battery by Volta in the previous year. Many suggestions were made, and theories were proposed, to account for its action, and it was remarkable that after a whole century of discussion and investigation these were still carried on along the lines originally suggested by Davy. His explanation of the voltaic battery, both in its essence and its elements, still held good to-day. Again, in advanced chemistry scientists are still concerned with attempts to discover answers to the questions: What is solution? What does solution do? How does it act? How is solution related to the production of electricity? These same questions, almost in the same form, were originally asked by Davy.

Prof. Dewar next made some remarks on the genius of Davy. He considered him one of the most remarkable geniuses that ever lived. He was practically self-taught; he had never seen any experiments made; all his scientific

Digitized by Google

knowledge and his very ingenious experiments were made from close study of the existing text-books. His early essay, so full of crude suggestions, "learned" him very much in the unsparing criticism to which it was subjected by the scientific world. It contained, however, the description of some very ingenious experiments, some of which the lecturer repeated. Thus his well-known experiment on the rubbing together of two blocks of ice in a closed chamber, in proof of the immateriality of heat, was described at this time, and thus anticipated Rumford's experiment having a similar object. Davy also described a second experiment, in which two metal plates were rubbed together, the heat generated being sufficient to melt a block of wax on which they rested. It was as a result of these experiments that Davy was led to enunciate his now famous theory that "heat is a mode of motion."

Davy was next heard of in connection with his appointment as scientific adviser to the Pneumatic Institution, founded by Dr. Beddoes, of Bristol, in which capacity he personally carried out a number of very startling experiments on nitrous oxide and other gases, so dangerous in their character that the modern chemist marvels that he survived. In 1802, Prof. Hope introduced Davy to Rumford, the founder of the Royal Institution, who immediately procured him an appointment there. He first worked at, and lectured on, the chemistry of tanning, and also that of agriculture, in both of which departments he discovered and invented many processes, a number of which are employed even to the present day.

It is, however, in connection with the voltaic battery, about which the minds of scientists were at that time much excited, that Davy was found at his best in devising decisive experiments and proposing suggestive theories. He showed: (1) two distinct metals were not absolutely necessary in the production of a current, but that two distinct electrolytes, in each of which the same metal is immersed, would act equally well; (2) a metal was not absolutely necessary, and that a non-metal, like carbon, in the presence of nitric acid was equally successful in producing a current; (3) water could be decomposed by a sufficiently strong electric current. This last experiment was suggested by the discovery of the electrolysis of certain liquid solutions by Nicholson and Cruikshank. Davy's experiments on electrolysis led him to ask the very important question whether they were the constituents of the same original particle which, after decomposition, appeared at the two poles. After much speculation and thought, he concluded that there was a "migration," as it would now be termed, and that, as a result of this migration, the "acid" portion of this particle appeared at the one pole and the "alkali" portion at the other.

(*To be continued.*)

PROJECTED ELECTRICAL POWER SCHEMES.

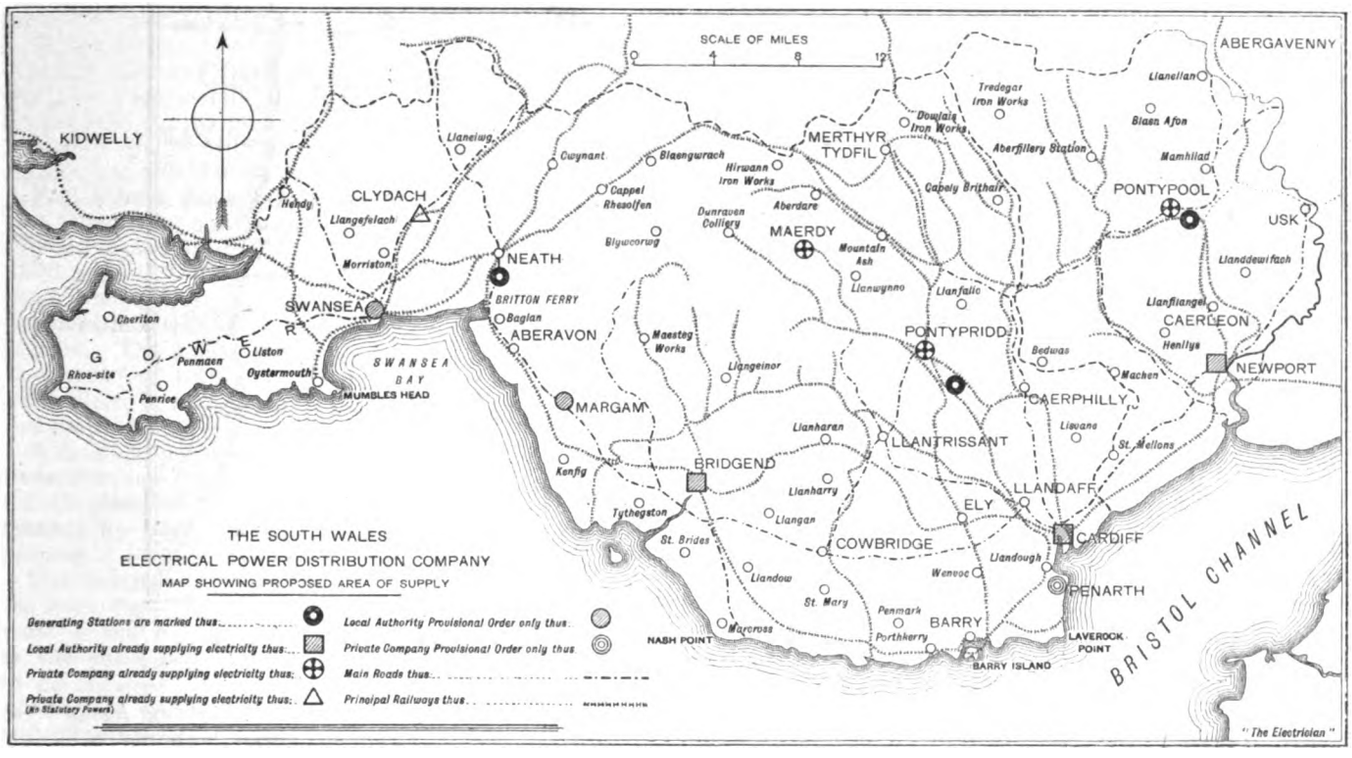
A number of bills have now reached the committee stage of their proceedings before the House of Commons relating to schemes for the supply of electrical power in bulk over extensive areas, in many cases involving entire counties. These comprise the following schemes:—

1. South Wales Electrical Power Distribution Co.
2. County of Durham Electric Power Supply Co.
3. Lancashire Electric Power Co.
4. Shannon Water and Electrical Power Co.
5. Tyneside Electric Power Co.
6. North Metropolitan Electric Power Supply Co.

At this stage in the progress of these important undertakings, it will be of interest to consider the main features of the various schemes. These are set forth in the following sections of this article.

1. The South Wales Electrical Power Distribution Scheme.

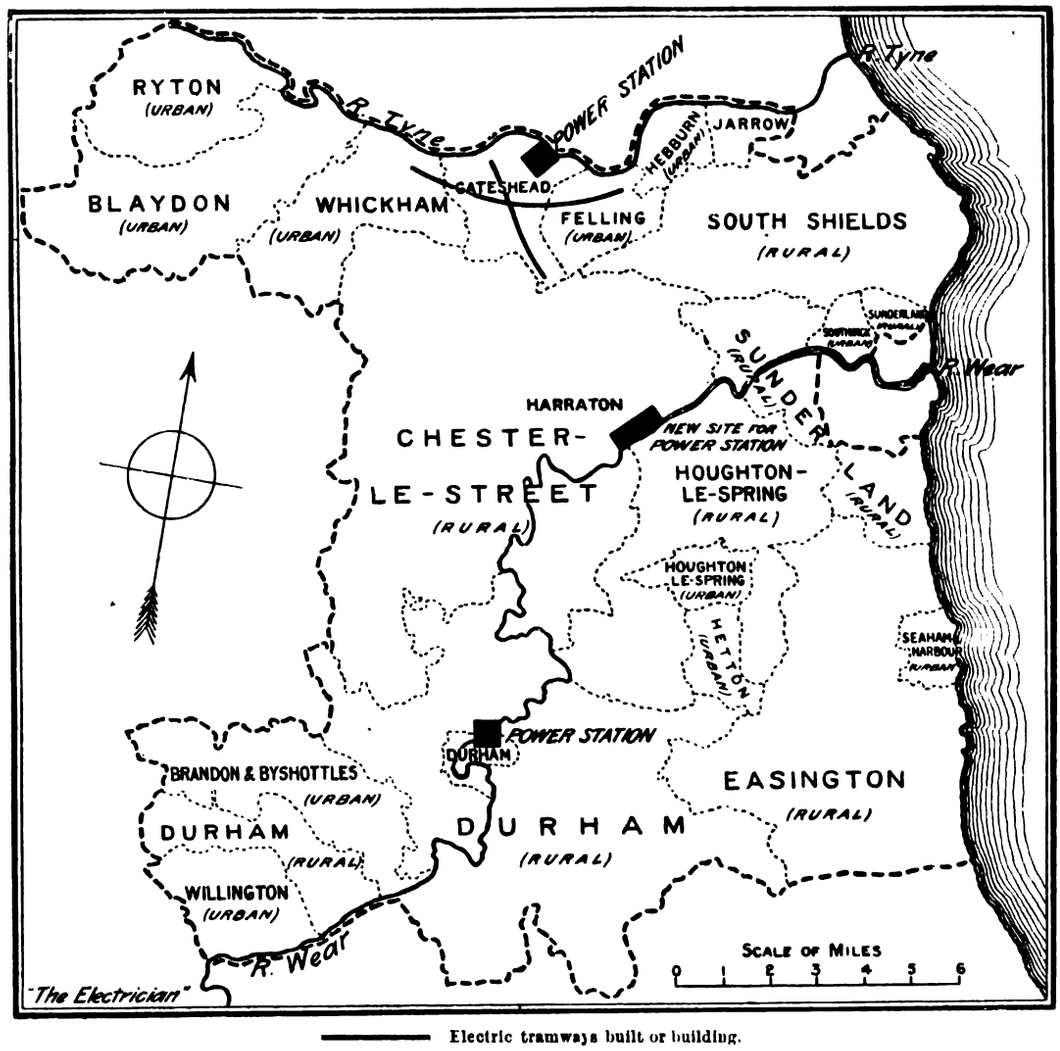
This scheme is for the distribution of electrical power over the area indicated in the accompanying map. The area comprises 1,050 square miles, and of this vast territory only 16½ square miles, that is to say, $\frac{1}{60}$th of the total area, is at present supplied with electricity. The promoters of the bill are Sir W. T. Lewis, Bart., Sir John Gunn, and Messrs. E. P. Martin, R. Forrest, A. Hood, A. T. Walker, A. Keen, E. Ruffer, E. W. Richards, T. F. Brown, F. L. Davis, T. Webb, R. Jones, Mark Robinson, J. Cory, P. Morel, H. Radcliffe, L. Wood, J. H. Simpson, G. F. Insole, and W. H. Lewis; and the Directors of the South Wales Electrical Power Distribution Co. are Sir W. T. Lewis and Messrs. E. P. Martin, R. Forrest, A. Hood, A. T. Walker, A. Keen, E. W. Richards, and T. F. Brown. The capital of the company is fixed at £1,000,000, of which £750,000 is share capital and £250,000 debentures. Under the scheme presented in the



MAP OF THE SOUTH WALES ELECTRICAL POWER DISTRIBUTION CO.'S PROPOSED AREA OF ELECTRICITY SUPPLY.

Digitized by Google

bill it is proposed to erect three electric power stations, viz., at Neath, Pontypridd, and Pontypool; and from these three stations there will be spread out an extensive system of mains for the supply of electricity over the whole of the area, which includes the entire county of Glamorgan and that portion of Monmouthshire which lies to the west of the river Usk. Within this area there are a large number of businesses and factories, &c., which might advantageously use electric power if supplied at a low price. Moreover, the area includes a very extensive colliery district enabling the generating machinery to be run at a very low cost as regards the price of fuel. Among the works which might be expected to utilise electric power and which abound in this district are collieries, steel works, tinplate and copper works, quarries, railways, tramways, engineering and ship repairing works, industrial factories and chemical works.



Electric tramways built or building.

MAP OF THE COUNTY OF DURHAM ELECTRIC POWER SUPPLY CO.'S PROPOSED AREA OF ELECTRICITY SUPPLY.

The promoters seek to obtain no monopoly. It is expressly provided in the bill that "Nothing in this Act contained shall confer or be construed to confer upon the company the exclusive right to supply energy within the area of supply." Moreover, the scheme is intended only for wholesale consumers, such as local authorities who seek to control their own local electrical supply. The "wholesale consumer" is defined by the bill as one who undertakes to take not less than 20,000 Board of Trade units per annum. The maximum prices fixed by the bill are as follows: (*a*) for any quantity not exceeding the equivalent of 400 hours' supply at the maximum power which has been demanded, at the rate of 4d. per unit; (*b*) for any further quantity exceeding the equivalent of 400 hours of supply at such maximum power, at the rate of 2d. per unit. It is fully expected, however, that power will be actually supplied at very much lower rates than the above: less, in fact, than 1d. per unit. The prices to be charged are to be regulated on the same principle as those under the Gas Acts, by which the company will have a direct interest in continuing to reduce its charges to the consumers, the profits distributed being made to depend upon the price charged.

This bill is drafted in terms which should prove acceptable even to the most "progressive" of local authorities. Any local authority may, at its option, take power at wholesale rates from the Company and distribute to consumers within its own area, or it may arrange with the company to undertake this business on behalf of the local authority. With regard to the powers to break up public streets, it may be stated that except where it is necessary to reach a factory the promoters seek no power to break up streets. Finally, the undertaking specified in this bill is to be subject to the usual form of the compulsory sale clause of the Electric Lighting Act of 1888, *i.e.*, the bill confers upon any local authority the right to purchase as much of the company's undertaking as is used for the supply of its district at the expiration of a term of 42 years, the price to be paid being the bare value of the plant without any allowance for goodwill. Without entering into a statement of the minor features of this promotion, sufficient has been said to indicate that it is a highly public-spirited and moderate scheme, and one that should certainly receive the assent of Parliament.

2. County of Durham Electric Power Supply Scheme.

This scheme provides for the supply of electricity in bulk over an area comprising the greater part of the County of Durham, the actual area proposed being indicated on the accompanying map. It will be seen that South Shields,

Digitized by Google

Sunderland, and a large district north of Hartlepools have been omitted from the area it is proposed to supply. The promoters of this bill are Messrs. W. L. Madgen, J. S. Raworth, E. Garcke and R. Percy Sellon. The proposed company is affiliated to the Electric Power Distribution Co., the British Electric Traction Co., and is associated with a number of electrical undertakings on the north-east coast, including the Hartlepool Electric Tramways, the Gateshead and District Electric Tramways, electricity supply in the municipal areas of Gateshead and Durham, the North Shields and District Electric Tramways and the South Shields Electric Tramways. The promoters seek power to supply electrical energy not only in bulk to local authorities, but also to anybody duly authorised by provisional order or possessing other statutory powers to supply or use electrical energy for any purpose whatever. It is provided that the local authority or other authorised undertaker in each section of the area shall lay its own system of distribution mains, the company merely supplying electricity in bulk to that section of the area. Arrangements have been made, contingent upon the passing of this bill, to supply the local authorities of Gateshead, Durham and other districts for the purposes of electric lighting and power supply. In some of these districts the actual house-to-house supply is to be undertaken by the company, provision being made whereby the local authority, if it so desires, can acquire the network of mains within its area at stated periods. The maximum tariff, as regulated by the bill, is based on the Wright system of charging; the rate for the first 100 hours per quarter of maximum demand will not exceed 4d. per unit, for all in excess the rate is to be not more than 2d. per unit.

(To be continued.)

CORRESPONDENCE.

MATTHIESSEN'S STANDARD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have recently had occasion to study the Report of the Committee on Copper Conductors, published in the *Journal* of the Institution of Electrical Engineers, January, 1900, page 169. The amount of searching required to get to the bottom of it is so great that I append the result of my own investigation, with the view of saving labour to some of your readers. The puzzle is to understand how "Matthiessen's standards" of 0·153858 and 0·150822 are arrived at by the Committee, having regard to the fact that these numbers are not given by Matthiessen.

A note appended to the report informs us that these figures have been calculated for 60°F. from the figures 0·1469 and 0·1440 given by Matthiessen for copper at 32°F., his own formula for temperature correction being employed for this purpose.

The investigator, looking up "Augustus Matthiessen" in the R. S. Catalogue of Scientific Papers, finds in two different volumes the references to a large number of Papers relating to the resistances of metals. Only two of them appear to be required for our purpose. One of these is in the *Phil. Trans.* for 1862, and contains at page 23 the formula $100 - 0{\cdot}38701\,t + 0{\cdot}0009009\,t^2$ for the conducting power at t°C. of a copper wire whose conducting power at 0°C. is called 100. This, when reduced to the Fahrenheit scale, agrees with the formula quoted in the Note, and when worked out for 60°F. give 0·941978 as the ratio of the resistance at 32°F. to that at 60°F.

The other Paper is in the *Phil. Mag.* for 1865, Vol. XXIX, where, at page 362, the statement is made that a hard drawn copper wire, 1 metre long, weighing 1 gramme, has at 32°F. a resistance of 0·1469 of the B.A. unit. This is one of the numbers quoted in the note. The other number, 0·1440, quoted for annealed copper, does not occur in the Paper, so far as I have been able to find; but on page 363 data are given for annealed and hard drawn, which imply that the ratio of their resistances is 2,057 to 2,104. This would give, not 0·1440, but 0·1436, and I am not able to explain the discrepancy.

Dividing 0·1469 by 0·941978 we get 0·1559485 as the resistance at 60°F., in terms of the B.A. unit originally issued, and taking that unit as 0·9866 of a true ohm we finally obtain 0·15386, which is in substantial agreement with the value adopted by the Committee for a hard drawn copper wire at 60°F. If we take the B.A. unit as 0·98656 we get 0·153853; and the adopted value 0·153858 lies between these two.

The value 0·150822 for annealed copper will be similarly accounted for when we know how the committee obtained the 0·1440. Perhaps the Honorary Secretary will kindly furnish this information.—Yours, &c., J. D. EVERETT.

Ealing, April 25.

P.S.—I have found two errata in the report: *Clarke* for *Clark*, and *square miles* for *square inches*.

We have sent a proof of the above letter to Mr. A. H. Howard, the hon. sec. of the "Committee on Copper Conductors," and have received the reply below. This correspondence is referred to in our editorial columns:—

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The figures attributed to Matthiessen for the comparative resistances of annealed and hard drawn copper vary considerably in the different reports:—

—	Hard drawn.	Annealed.	Per cent. increase of H.D.
Phil. Mag., May, 1865, p., 363. Resistance	0·02104	0·02057	2·284
Phil. Trans., 1860, p. 86. Conductivity ...	95·31	97·83	2·644
Phil. Trans., 1864, p. 197. Conductivity...	99·95	102 21	2·261
"Reports of Electrical Standards," F. Jenkin, p. 227. Resistance	0·1469	0·1440	2·014

As the experience of the members of the committee showed that the latter figure was the most accurate for modern commercial copper, and as the table in Prof. Jenkin's book had been adopted by the Post Office and by many manufacturers as a basis, the figure of 0·1440 B.A. units for one metre gramme of annealed copper was chosen, and the various constants were found by simple calculations which hardly need explanation.

The Committee were engaged in fixing a commercial standard, and not in accurate scientific research, so that the question as to which of Matthiessen's investigations was the most reliable did not concern us; but only which was in best accord with present conditions.

It may be of interest, however, to point out that Matthiessen did not determine a practical standard of resistance for copper, inasmuch as he omitted to ascertain the specific gravity of the wire used. In one of his later Papers he refers to this omission as a grave error. The result is that some specific gravity must be assumed in order to find the resistance of a wire of any given diameter; and as the specific gravity of copper varies from 8·89 to 8·95, a possible error of nearly ¾ per cent. may be introduced at once.—Yours, &c.,

A. H. HOWARD,
Hon. Sec. Committee on Copper Conductors.

London, May 1.

PARLIAMENTARY INTELLIGENCE.

THE POST OFFICE AND THE TELEPHONE.

In the House of Commons on Friday last, on the vote to complete the sum of £8,843,605 for the Post Office, Sir C. Cameron moved the reduction of the vote with the object of calling attention to the action of the Department in connection with the telephone. He said the policy pursued appeared to him to be contrary to the intention of Parliament, unfair to the municipalities, and at variance with the policy connected with the telephone scheme inaugurated last year. The object of Parliament had been to safeguard the powers of municipalities controlling the streets and roads against the action of private trading companies, while affording facilities for the Post Office. In 1897 the National Telephone Co. applied to the Glasgow Corporation for liberty to lay underground telephone wires, but the Corporation had a great objection to allow outside bodies the right of breaking up streets, and refused the application, although the company

Digitized by Google

offered a considerable sum for the privilege. At the same time a similar application was made by the Post Office, and the Corporation offered to grant the permission sought on condition that it was not made use of simply for the benefit of the National Telephone Co. The Post Office objected to this condition, and in 1898 served the Corporation with a notice under the Telegraphs Act requiring it to grant the facilities. This led to a dispute, and the question was referred to the sheriff for decision, and he, early in 1899, declared in favour of the Post Office. An appeal to the Railway Commissioners confirmed the sheriff's decision. He held that it was not in accordance with the policy recently approved by Parliament for the Post Office to step in and take away a right in public streets which conferred on municipalities certain advantages over their competitors.

Mr. J. WILSON said the Glasgow Corporation objected to the National Co. or, in fact, any private company coming in behind the Post Office and getting the benefit of privileges that Parliament had conferred upon the Department, and the Corporation, he contended, were acting in the interests of the community. The citizens should not be asked to put their money into the pockets of the company when they could obtain a better service from the local authority.

Mr. URE said there was no community which had been worse served in regard to telephonic communication than Glasgow. There were ten times more complaints per head from Glasgow than from Birmingham, and seven times more than from any other commercial community in the country, and this was certainly not attributable to the overhead system and the absence of the twin-wire circuit. The Corporation had no objection to the Postmaster-General opening up their streets, but objected to giving him such powers for the benefit of the National Co.

Sir J. WOODHOUSE said general apprehension prevailed, on the introduction of the Telegraphs Bill in 1892, that the National Co. might be placed in such a position as would prevent competition. In consequence of this feeling and of representations from municipal bodies, it was provided by that bill that, notwithstanding anything in the Telegraph Act of 1878, a licensee should not exercise any powers without the consent of the municipal authority directly interested, and should be subject to such terms and conditions as the local authority might attach to its consent, and should comply with any regulations of the local authority in force in relation to telegraph lines. He felt that in Glasgow's case the Post Office had done indirectly what the House by this provision intended should not be done. The House ought to show its repugnance of the action taken by the Post Office.

Mr. STUART WORTLEY thought to refuse all powers to the only telephonic organisation in existence when the Act was passed was an extreme course. The inability to arrive at an arrangement was little creditable to either the Corporation or the company, and was injurious to the public interests.

Mr. PARKER SMITH considered there was room in Glasgow for both the company and the Corporation; but if the municipality wished to try the experiment of establishing its own telephones they would not be unduly restrained by Parliament or the Post Office.

Mr. HANBURY, in reply, said the question of the telephone service in London, although it concerned wayleaves, was an entirely different matter to that of Glasgow. In London, partly owing to snow storms, and partly to the decision of the Duke of Bedford, the service of the National Co. in certain parts of London necessarily became inadequate. This difficulty arose mainly in connection with overhead wires. It was contended that it should be possible to lay these wires underground, and complaint was made against the London County Council that they would not give their permission for this to be done. Under ordinary circumstances, perhaps, the Council would be carrying their control over the streets too far to refuse that concession to the public convenience, because there could be no doubt that a telephone service, whether by the State or by a company, was a great public convenience, and the Council would have to take that point into consideration. But the State was itself engaged in constructing a system of telephonic communication all over London, and it was obvious that in the public interest there should be inter-communication between these two systems. If that could not be brought about, then the difficulties of having the two systems working side by side, especially over so large and important an area as London, would be very serious, and therefore everything that was fair and reasonable to the company should be done to require the National Telephone Co. to work in inter-communication with the Government telephone system. This being so, the Council were not acting at all unreasonably in the matter; they recognised that they ought not to deny the use of underground wayleaves from any spirit of pique or opposition to the National Co., or from any inflated idea as to their rights over the streets. They had the power, if the company was reasonable, to give that company every facility to provide, in conjunction with the State, as good a telephone service as existed anywhere. The Council, acting entirely in the public interest, held that it was doubtless in the public interest that the company should have facilities for placing their wires underground, but it was also equally in the public interest that the company should work in inter-communication with the Post Office service, and therefore the Council were prepared to grant such facilities in the interests of the public, if the company would recognise that it had to establish its service for the general benefit of the metropolis. With regard to Glasgow, the Corporation of that city had put themselves in the forefront of Corporations, and had, in his opinion, set an excellent example to other municipalities. He had himself always tried to deal fairly with the National Telephone Co., but undue facilities ought not to be given to any one private company. When the National Co., long before competition was threatened, applied to the Corporation of Glasgow for power to establish a telephone service, the Corporation had the undoubted right to refuse that permission, but they gave the permission, and had to bear whatever consequences such permission involved. After the service was started, an agreement was entered into between the company and the Post Office under which the company could not interfere with the streets, and could not lay underground wires and this agreement must be rigidly respected. There was misapprehension as to what the Post Office had actually done. The circular recently issued by the National Co., if he read it rightly, implied that the Post Office had entered into an agreement with the company, binding the Post Office to lay wires for them wherever they chose to go. If that was the meaning conveyed in the circular, then the company were entirely wrong. The circular was, in fact, a most misleading document. The agreement between the company and the Post Office did not bear out what that circular said. Under the agreement the Post Office were required to lay down wires between exchange and exchange, and nowhere else, and if the agreement, and nothing beyond the agreement, was carried out it would not prejudicially affect the undertaking of the Glasgow Corporation. The Corporation would have had fair ground for complaint if the Post Office had laid wires between the exchanges and the subscribers, but that had not been done. That agreement was executed before there was any competition impending, and though they might regret that that agreement had been come to, it must be faithfully carried out. It did not, however, operate to the disadvantage of Glasgow Corporation. There was a definite agreement drawn up between the National Co. and the Post Office, and he believed the actual date of signing that agreement was 1895, but the original heads of the agreement were drawn up in 1892.

Mr. T. SHAW said the circular undoubtedly made a claim which, upon investigation, could not be sustained.

Sir J. FERGUSSON hoped the hon. and learned member (Mr. Shaw) would not, in calmer moments, urge the Government to set aside the agreement of 1895. The National Telephone Co. expected the Government to do nothing beyond the agreement of 1895, and what the Government proposed to do in Glasgow was to get the trunk wire and save the telegraph revenue.

Mr. BURNS denied that the National Co. had been subjected to unreasonable restrictions by the London County Council. When Glasgow was asked to confer on a private company like the National Co. with its past history and present conduct of affairs, the same privileges and advantages they might reasonably give to the Post Office, he contended that the Corporation of Glasgow would be neglecting their duty if they did not differentiate between a public department and a private company.

Sir A. ROLLIT said there had been a deal of misconception in the whole matter before the House. He would not question the divine rights of local authorities over the streets in their localities, but that right was subject to the law of the land, to agreements which had been entered into by a public department even if only with a private company, and, what was absolutely paramount, to the public interest. What was the basis of the new departure with regard to the telephones? That basis was "free and equal competition"; but the conditions now sought to be imposed, taking the case of London first, would render that free and equal competition impossible. The terms to be compulsorily accepted by the company were to be those formulated by the Government, whatever they might be—that was, they were to compulsorily adhere to unknown terms. Such conditions would be a gross injustice to an established interest and at the same time a grave disadvantage to the public.

Mr. BURNS said he hoped that until the National Telephone Co. granted the same facilities for inter-communication which its own subscribers would receive it would meet with continual hostility in the House of Commons and the County Council, and that every municipality would boycott it.

Mr. McCRAE thought there had evidently been considerable misunderstanding of the attitude of the Post Office, and Mr. Hanbury's statement would be much appreciated by the Corporations of Edinburgh and Glasgow. The control of the streets by the municipal authorities went to the root of municipal efficiency.

Mr. CALDWELL said the National Co. established itself in Glasgow without consulting the Corporation at all. He contended that the agreement between the Post Office and the company was not a valid agreement, or one that could be enforced upon the Corporation of Glasgow.

Sir J. FERGUSSON reminded the House that this agreement of 1895 was part of the original agreement detailed to Parliament in 1892, when it was perfectly understood, and objected to by no one. Its terms were carried out by succeeding Governments on the understanding that they had received the full assent of Parliament.

In the House of Commons on Monday, Mr. Kimber asked the Secretary of the Treasury what was the cause of the delay in announcing the telephonic facilities proposed to be offered by the Postmaster-General, and when these arrangements were likely to come into operation; and if he was aware that the National Company were serving notices upon telephone subscribers that they might at any moment have their telephone communications withdrawn in consequence, as the company alleged, of the refusal of the London County Council to give the company underground wayleaves, whereas the Council had in fact offered to give such leave if the company would give telephonic inter-communication.

In reply, Mr. HANBURY said that it was not considered expedient yet to announce the actual rates of subscription to Post Office telephone exchanges until further progress had been made. The Postmaster-General had no official means of knowing what notices were sent by the National Co. to their subscribers except from the ordinary sources of information. But Mr. Burns on Friday stated in this House the terms upon which alone the County Council would grant wayleaves to the company. The conditions imposed were wholly in the public interest, and he was in entire agreement with the Council in the course they were taking. He hoped the arrangements being made by the Post Office would come into operation during the autumn or before the end of 1900.

UNDERGROUND TELEGRAPH CABLES.

In the House of Commons on Tuesday, Mr. Hanbury stated that if the underground telegraph cable from London to Birmingham proved successful, the Postmaster-General would consider in what other directions underground wires could with advantage be laid down, with a view to increasing the stability of the telegraph system.

MUNICIPAL TRADING.

In the House of Lords on Tuesday, the Earl of Morley moved that a committee of five lords be appointed to join with a committee of the House of Commons, to consider and report as to the principles which should govern powers given by bills and provisional orders to municipal and other local authorities, for industrial enterprise within or without the area of their jurisdiction.—The motion was adopted.

It is stated that the following have been appointed to represent the House of Commons on the Joint committee of both Houses on the question of municipal trading:—Sir E. Hoare, Sir L. Lyell, Sir W. Foster, Mr. Grant Lawson, and Mr. Hobhouse.

COUNTY OF DURHAM ELECTRIC POWER BILL.

The Committee appointed by the House of Commons to consider the provisions of bills dealing with the supply of electric power sat for the first time yesterday (Thursday), Sir J. KITSON presiding. The other members of the committee are Sir A. Scoble, Mr. Bartley, Mr. Ashton, Mr. Howard, Mr. Billsom, Col. Long, and Mr. Bonham Carter (referee). The first bill to be dealt with was that introduced by the City of Durham Electric Power Supply Co. (A sketch map of the Durham Co.'s proposed area of supply is given on page 58 of this issue).

Mr. Balfour Browne, Q.C., Mr. Worsley Taylor, Q.C., and Mr. Moon appeared for the promoters, while the petitioners were represented as follows: The Felling District Council and the Hebburn District Council by Mr. J. D. Fitzgerald, Q.C., and Mr. J. D. Williams; the promoters of the Tyneside Electric Power Bill of the present session by Mr. Pember, Q.C., Mr. C. Baggallay, Q.C., Mr. H. Lloyd, and Mr. Frere; and the Lambton Colliery Co. by Mr. E. H. Lloyd.

In opening the promoters' case, Mr. BALFOUR BROWNE said the bill was one for incorporating and conferring certain powers on the County of Durham Electric Power Supply Co., and for other purposes. It was proposed to establish at Gateshead a central station for generating electric power, and to supply therefrom energy in bulk to local authorities over a wide district. The bill was promoted by certain gentlemen who already had a large interest in electricity in Durham. The promoters were connected with the Gateshead tramways, authorised by an Act of last session, and by the Gateshead Light Railway Order of 1899, and with the electric lighting of Gateshead and Jarrow. They were also interested in the electric lighting order which the Corporation of Durham had agreed to transfer to them. They asked for power to supply electricity in bulk to a large area in the County of Durham, including Gateshead, Jarrow, Durham City and Seaham Harbour; South Shields and Sunderland having been excluded at the desire of the Corporations of those places. the whole of the local authorities whose districts were included in the bill were favourable, with the exception of the District Councils of Felling and Hebburn, both Tyneside authorities. The intention of the promoters was to put up a central generating station at Gateshead from which it would be possible to supply electric energy at very low prices indeed. They took power to supply any lighting authority, any statutory authority for the supply of electric energy, and any local authority, company, or person, authorised by Act of Parliament to use electrical energy for any prescribed purpose. Under the bill they would not be able to distribute electricity in competition with any local authority, but they thought that they would be a most useful assistant to any local authority. By manufacturing on a very large scale they would be able to manufacture exceedingly cheaply, and to supply a district like that of Houghton-le-Spring, for instance, at a rate much lower than that at which the district could manufacture for itself. There was at the present time a good deal of doubt in the public mind as to how far municipal corporations ought to be allowed to go in the matter of trading, and he asked the Committee to say that the supply of electricity to this district was more likely to be better done by a company than by a corporation—that the supply of power for manufacturing and traction purposes could be more properly trusted in the hands of private enterprise than in the hands of a corporation. A corporation must buy its coal if it made its own electricity, and he could not see why, instead of buying the coal it should not be allowed to buy its electricity in bulk. In the county of Durham the local authorities generally took the companies view of the matter. They did not want to become large manufacturers, but they did desire to retain in their own hands the distribution of the power. Of course the alternative, if electric power was needed, was to have a manufacturing station in each district, and it was obvious that the expense of such a system would enormously increase the cost of the production of electricity. The result would be that such a system would never be carried out, because electricity could not be supplied for power purposes unless it competed successfully in other kinds of power production. The company placed themselves under the obligation of supplying electricity to all the local authorities in the district who demanded it, but they could not compel any authority to take a single unit. The company could be even compelled to supply part of a local authority's demand if an arbitrator thought that a partial supply was reasonable. It was proposed to take power to break up streets and roads, and all the local authorities except Felling and Hebburn assented to the proposal. The estimated cost of manufacture would be little more than a halfpenny per unit, and the promoters expected to be able to supply energy at 1d. and certainly at not more than 1½d. There was a considerable margin for profit therefore, even on the £457,000 which it was proposed to expend. The total amount of the company's capital would be £500,000.

Mr. FERRANTI, examined by Mr. Moon, said he was an electrical engineer, and was also a manufacturer of all the machinery necessary for carrying out such a scheme as that embodied in the bill, his works being at Hollinwood, Lancashire. He was of opinion that if electricity could be cheaply supplied it would be applied to many purposes for which in this country other motive power was now used. In many districts in America there was a cheap supply of power on a great scale, and on the Continent of Europe such a state of things was general: there were an immense number of large institutions for supplying power wholesale over large districts. The manufacturers on the Continent readily took advantage of it, and were enabled, largely on account of this, to compete more severely than ever with the manufacturers in this country, who had not such advantages. He did not think that a better thing could be done for the small manufacturers in this country than to supply them with cheap mechanical power, and he was sure that such men would employ such power if they could obtain it advantageously.

The CHAIRMAN said he thought the committee would admit that it was an advantage to have a cheap supply of electric energy.

Witness went on to say that he did not think there could anywhere be better conditions for a cheap supply of electricity than would be provided by the bill. It would be possible for a generating station on the Tyne to supply the whole district cheaply and well. The load factor would mainly depend on the diversity of the demand for energy. By dealing with a large area, and supplying electricity for many purposes, a company would stand the best chance of getting the longest possible utilisation of the power per day. The purposes for which the power supplied by the company would be used would be principally (1) electric lighting, (2) the running of tramways, and (3) the driving of motors in works, or wherever they might be required. These three separate kinds of demands were calculated to give the best load factor it was possible to obtain. He had worked out a scheme for supplying a maximum demand of 9,000 kilowatts or 12,000 horse power. The total power of the installation, would be, however, greater than that because a reserve power was provided. Roughly, the maximum power of the engines and boilers would amount to 20,000 H.P. The whole generating plant would cost £297,000. The cost of transmission would be £160,000 and with contingencies the total cost of the scheme would be £500,000. The "maximum demand" of 9,000 kw. was taken as being the demand on which the company could start business and by no means represented the demand of which the district was capable. It referred simply to the amount of plant provided for making a start. 2,500 kw. were put down for lighting purposes. The company knew that 1,000 kw. would be required for tramway purposes already arranged for, and the balance of 5,500 kw. would be available for motive power. This proportioning of load was important, because therefrom was obtained the probable load factor and therefore the commercial results obtainable. It was estimated that the load factor would be 25 per cent. The 2,500 kw. for lighting purposes were put down as an 8 per cent. load factor. The 1,000 kilowatts for tramways were put down at 40 per cent., though in a good many cases the tramway load factor was better than that. The 5,500 kilowatts for power purposes was put down at 30 per cent. He considered that all these figures were perfectly safe, and in combination they made a load factor of 25 per cent. The nett result of the calculations he had made as to the cost of generation was that it would come to 0·44 of a penny per unit. The cost of transmission would require the addition of about 0·2 of a penny per unit. The total result was that the cost would be something under 0·7 of a penny per unit. With an average price of 1¼d. per unit, the company would get a nett revenue of about £104,000. The total working expenses at 0·7d. per unit would amount to £60,000. This would leave £44,000, which was enough to pay 8 per cent. on the capital, and leave £4,000 to carry forward. 1¼d. would be a low enough price to tempt almost everybody—certainly everybody ought to utilise to its full capacity the plant to be provided now, and much more besides. It was proposed to adopt the extra high-pressure system, which electricians had found to be the most economical one for transmitting a large power over a long distance without serious loss. A proportion was proposed to be transmitted at 10,000 volts and a proportion at 5,000 volts; but he was of opinion that the scheme would probably be carried out at one pressure—namely, 10,000 volts, as there was not the least difficulty in using that pressure.

In cross-examination by Mr. J. D. Fitzgerald, WITNESS said that he was not interested in the bill in any way. It was necessary for the success of the scheme that the company should be able to lay their mains in Felling and Hebburn, but of course if those districts did not want to avail themselves of the supply offered them they need not do so.

The Committee then adjourned till to-day (Friday).

BAKER-STREET AND WATERLOO RAILWAY BILL.

The Select Committee of the House of Commons, presided over by Sir Ughtred Kay Shuttleworth, on Tuesday considered the measure promoted by the Baker-street and Waterloo Railway Co. for the extensions of their authorised line, the erection of a generating station, and other purposes,

The promoters were represented by Mr. Worsley Taylor, Q.C., Mr. E. Page, Q.C., and Mr. J. Shaw. The Metropolitan Railway Co., the only petitioners applying by counsel, were represented by Mr. Littler, Q.C., Mr. Balfour Browne, Q.C., Mr. Freeman, Q.C., and Mr. F. G. Thomas.

Mr. WORSLEY TAYLOR, Q.C., for the promoters, said powers were now sought to make extensions at both ends of the company's present authorised line. It was proposed to extend the railway on the northern side, from the Great Central Railway terminus as far as the Paddington station of the Great Western Railway, and on the southern side to construct an extension from Waterloo to the Elephant and Castle. The length of these extensions would be about 2¼ miles, and subways would be constructed to give access to the Great Western Railway terminus at Paddington, and to the City and South London, and London, Chatham, and Dover Railways at the Elephant and Castle. The committee of 1893,

Digitized by Google

which had considered the question of these electrical lines, had reported that it was advisable to relieve the congestion of the London streets, by connecting the great railway termini by means of these lines to be worked by electricity. The original scheme of the Baker-street and Waterloo Railway was before that committee, which had approved of it as an instalment. The Elephant and Castle was the second most congested spot in the metropolis, and that congestion would be relieved under the bill, as would also that at Charing Cross, Piccadilly Circus, and other places. Under the original bill of the company there was to be a generating station for the working of the line at Waterloo Station. Subsequent to the passing of that bill there came the Waterloo and City Railway, and it was found that the land scheduled for the generating station was necessary for the purposes of the South-Western and Waterloo and City Railways. There was, however, a convenient site available in the St. George's-road, Southwark, and evidence would be given that no nuisance would be created by the erection of the generating station there. There was no opposition to the use of this site for the purpose. By the bill, Parliament was asked to do what had been done in the case of other undertakings of a similar character. The learned counsel then gave a financial history of the company, and said that the London and Globe Finance Co. had practically become the dominant parties in this undertaking. The capital now asked for for the works to be carried out under the bill was £1,000,000 of share capital, and further borrowing powers of £333,000. A contract had been entered into between the London and Globe Co., under which they were to acquire the land for the generating station and to construct and equip the extensions in the same way as they had constructed and equipped the original line. Their payment for that would be £336,000 in shares, with a corresponding proportion of debentures, and there would be a margin, if everything went right, for the London and Globe Co. of about £95,000 for the whole risk taken. The present need of the Baker-street Co. was a generating station, and to get to one erected on the proposed site in St. George's-road an extension would have to be made without which the authorised line could not be worked. But if the line were extended so far a very small further capital expenditure would extend it as far as the Elephant and Castle.

Evidence was then given in support of the bill.

Mr. GALBRAITH, C.E., said he had been consulting engineer to the London and South-Western Railway for 40 years. He was one of the engineers for the Baker-street and Waterloo Railway Co. Witness then gave evidence as to the difficulty in raising the capital for the construction of the various electrical underground railways directly from the public. In the case of most of the electrical railways, the capital had been underwritten. In describing the works proposed by the bill, witness said there would be a new station at the Edgware-road besides the terminal one at Paddington. He anticipated that the traffic would be very large. They proposed to put the station at the Elephant and Castle on public ground, as had been done at the Bank, and was proposed to be done at Charing Cross. The cost of doing this with the necessary subways would be £9,000, and the local authorities had agreed to assist them in carrying out the work.

Mr. Wilkinson, general manager of the Great Western Railway Co., Mr. C. J. Owens, general manager of the London and South-Western Railway Co. and Sir William Pollitt, general manager of the Great Central Railway Co., gave evidence in support of the proposals of the bill.

Mr. HARE, deputy-chairman of the promoting company, said there would be no difficulty in obtaining capital to carry out the proposals of the bill as his company had made a contract with the London and Globe Co., which was a very strong body.

Witness was cross-examined for the Metropolitan Railway Co. to show that the London and Globe Co. would make a very large profit on the undertaking, if not an undue one.

Sir BENJAMIN BAKER, C.E., engineer to the scheme, said that on his advice the contracts had been prepared four years before the London and Globe had had anything to do with the line. There was no possibility of "plunder," as had been suggested, in the interests of the London and Globe Co. The public would get the new line, over the whole six miles of which they would be carried for 2d. He had told the London and Globe Co. that the electric installation would cost more than they had been told, and they accepted his figures.

Sir J. WOLFE BARRY, K.C.B., C.E., was called in support of the petition of the Metropolitan Railway Co. against the bill. He said that the extension of this line to Paddington really meant a complete reversal of the original idea, which was for a north and south line. It was now sought to make it an east to west line within a quarter of a mile of the Metropolitan Railway, obviously to be further extended to the west, and perhaps to the east also. Last year the Metropolitan and Metropolitan District Railways each subscribed £10,000 towards working experimental electric trains between Earl's Court and High-street, Kensington, and employed Messrs. Siemens Bros. and Co. to put down the necessary works. Electric conductors had been laid along the rails so as not to interfere with the steam locomotives. The new electric trains were complete, together with the new electric motors. The electric trains would carry more passengers than the ordinary trains, and they had been run experimentally for some weeks, and had been inspected by the Board of Trade, and as soon as the Board's report had been received the trains would be run for the conveyance of passengers. These experiments had been a conspicuous success. Trains weighted with iron to represent the heaviest loads carried on the line had been run, and it had been found that the electric motors could be stopped and started more quickly and were more powerful than steam locomotives. The average rate of travel by the new trains would be considerably greater than with the steam locomotives. Both companies were completely satisfied with the experiments, and they had a keen interest in extending the use of electricity as their lines suffered very much from the lack of ventilation.

Mr. J. BELL, manager of the Metropolitan Railway Co., having given evidence against the bill, counsel addressed the Committee.

The Committee ultimately decided to pass the preamble of the bill.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY BILL.

A committee of the House of Commons yesterday commenced the consideration of this bill. Mr. A. H. Brown presided.

Mr. PEMBER, Q.C., for the promoters, said the measure arose out of the provisional order bill passed last year. That order contained one special provision, in consequence of which the company had again to come before Parliament. That provision was that the company should provide within two years a new generating station for the supply of the City of London such site to be approved by the City Corporation. The site had been fixed in the borough of West Ham at a point which was well away from any residential district, and the object of the bill was to authorise the acquisition of this site and the laying of the mains from the generating station to the City. There was also a proposal to supply electricity in bulk to any local authority on the line of route to the City. There were altogether 11 petitioners against the bill, one of them being the Corporation of West Ham, who objected on various points of detail. The London County Council also petitioned, boldly declaring that no public necessity could be shown for the powers authorised by the bill. The other petitioners included the Whitechapel District Board of Works.

Among the witnesses called was Mr. W. H. PATCHELL, the company's engineer, who stated that the site of the proposed generating station had an area of 7½ acres, and the mains would extend from West Ham for about 3¼ miles to the City boundary, through Poplar, Mile End, and Whitechapel. After serving the City, the mains would extend to parts of the West End of London.

After hearing further evidence the Committee adjourned till to-day.

SOUTH LANCASHIRE ELECTRICAL TRAMWAYS BILL.

Yesterday (Thursday) a Committee of the House of Commons, under the presidency of Mr. Seale-Hayne, sanctioned the incorporation of the South Lancashire Tramways Co., the members of which are Messrs. James B. Atherton, Jacob Atherton, and William M. Brigg. The company is formed to construct about 67½ miles of tramway in Burton Wood, Newton-in-Makerfield, Westhoughton, Bolton, Tyldersley-with-Shakerley, Worsley, Swinton, Eccles, Haydock, Pemberton, Abram, Ince, Hindley, Little Hulton, Golborne, Ashton-in-Makerfield, and Astley. The committee also sanctioned the raising of capital to the amount of £1,100,000.

Mr. BALFOUR BROWNE, Q.C., for the promoters, said there was really very little opposition to so large an enterprise. The proposed tramways numbered in all forty-five, and would form a complete system connecting large centres of population and affording communication by tramway with Liverpool to the westward and Manchester to the eastward. The gauge would be 4ft. 8½in., and the undertaking would be completed in four or five years. The generating station would be at Leigh, the centre of the district. Owing to the expense of electric equipment, the promoters thought the 21 years allowed by sec. 23 of the Tramways Act did not give them a fair chance of recouping their capital, and they therefore asked for a 35-year period, as allowed under the Light Railways Act, the promoters reserving the right to run over the section purchased by any local authority. Most of the local authorities were in agreement with the bill. The three great railway companies—London and North-Western, Lancashire and Yorkshire, and Great Central—originally opposed the bill on the ground of competition with their systems, but they had withdrawn their opposition, having evidently become convinced that the tramways would act as feeders to their lines. Of the 29 local authorities in the area of the proposed tramways, only four were opposing—Ashton-in-Makerfield, Swinton, Eccles, and Worsley. The promoters had promised the local authorities in some cases to widen the roads, and in others also to light the tram route by electricity. The length of line to be constructed was 44 miles of single line and 23 miles of double line, and would extend over 67 miles of road, of which 54 miles were in the districts of local authorities who were not opposing. Within the area proposed to be covered was a population of 440,000 people, and, reckoning Liverpool and Manchester, over 2,000,000 people.

Mr. JAMES ATHERTON, managing director of the British Insulated Wire Co., one of the promoters, stated that the means of inter-communication in South Lancashire had for a long time been inadequate, and the proposed scheme had been formulated by him to meet what he considered a public need. Such a system of tramways was, in his view, the best way of dealing with congested districts, and would serve the convenience of South Lancashire well. He denied that the promoters intended, as soon as the bill had passed, to transfer the scheme to a company.

Mr. LEWIS COWARD, Q.C., pointed out that the bill contained conceded clauses committing the promoters to the widening of 100 thoroughfares as well as the lighting of the entire route by electricity. Had the promoters, he asked, power to execute such work?

Mr. ATHERTON said he understood the powers were in the bill. If not, they would go to Parliament for them.

Colonel MILWARD (a member of the committee) asked if the promoters were going to light the whole line of route, town and country?

Mr. ATHERTON: Yes. It will, we think, benefit the tramway by facilitating the traffic at night.

Mr. J. E. WALLER (Messrs. Kincaid, Waller and Manville), engineer for the scheme, estimated that £488,559 would be required for the construction of the tramways. The electric current for lighting the line of route would cost less than ¾d. per unit. The posts for overhead wires would be utilised for the public lamps. The total cost of these tramways was the amount provided by the bill for capital powers—£1,100,000. The permanent way would cost £1,520 per mile. The original estimate for road widenings was £45,000, but an additional £70,000 had been imposed by the concessions made to local authorities since the bill was deposited. The overhead electric equipment would cost £70,500.

Other evidence having been tendered, and most of the opposition having been withdrawn, the committee, as mentioned above, sanctioned the bill.

GREAT GRIMSBY STREET TRAMWAYS BILL.

A House of Lords committee has passed the bill of the Great Grimsby Street Tramways Co., which confers powers to construct new tramways in the Cleethorpes district, to work the lines by electricity or other mechanical power, and to give effect to a provisional agreement entered into between the company, and the Corporation from which the latter body desired to recede. The committee decided that the agreement between the Corporation and the company must stand, and remain a part of the bill. They also decided not to permit the proposed crossing of the Great Northern Railway.

LEGAL INTELLIGENCE.

City of London Electric Lighting Co. (Ltd) v. Corporation of London.

This case came before Mr. Justice Farwell in the Chancery Division on Friday last.

Mr. CRIPPS, Q.C., said the action was brought to determine whether certain contracts in which plaintiffs were interested, and of which they were assignees, were valid and binding between them and the City of London. The question turned on the construction of the Commissioners' Acts of Parliament of 1848 and 1851. The contract in question was entered into in 1890 or 1891, and had been acted upon by both parties, and the plaintiff company had expended a very large sum upon the understanding that the contract was binding and effective. There had been litigation before Mr. Justice Kekewich, in which certain terms of the contract were considered on the basis that it was a binding contract. It was only lately that the suggestion had been made by the Corporation that the contract was null and void. There were three separate contracts for the lighting of the central, eastern and western areas of the City. As regarded the central and western, at the time the contracts were made there were among the Commissioners of Sewers certain aldermen and common councilmen who were also shareholders in the Brush Electrical Engineering Co., with whom the contracts were originally made, and the suggestion was that if they were members of the syndicate or company which entered into the contracts *ipso facto* the contract was null and void, and for that contention the defendants relied upon the terms of the statute. The third contract was entered into when no member of the Commissioners of Sewers or alderman or common councilman was a member of the contracting syndicate or company; but at some time subsequently, certain shares were taken in the plaintiff company by members of the Corporation, and the suggestion was that if, even after the contract had been entered into, any City councillor or alderman took shares, that *ipso facto* rendered the contract null and void. Counsel submitted that, although at the time of two of the contracts being made some of the Commissioners were shareholders, that fact did not nullify the contract. In the case of the Eastern district, the original contract became vested in the plaintiff company, of which some members of the Corporation were shareholders, and the defendants now said that that fact made the contract null and void *ab initio*. The plaintiffs therefore asked a declaration that all those contracts were valid. The defendants said that, under the Commissioners of Sewers' Act of 1848, if any alderman or common council man was directly or indirectly interested in any contract for works, &c., with the Commissioners, such contracts became null and void. The learned counsel submitted, however, that this provision was limited in its operation, and did not apply to the circumstances of the contracts now in question. He contended that it was intended only to apply to the case of persons directly carrying on their own or a partnership business, and not to the case where the person was a shareholder only in a public company, and who took no personal step to effect the procuring of the contract. An alderman and a common councillor might hold a share in the gas company, the electric lighting company, or the New River Co.; then if the defendants' contentions were correct, upon an information being laid, the City might be plunged in darkness, and have its water supply stopped. He submitted that that was an unreasonable contention.

Mr. SWINFEN EADY, Q.C., for defendants, said he disputed altogether the statement which had been put forward by Mr. Cripps that a shareholder in a company was not a person interested in that company. The true construction of the contract was that it was a contract to execute "works." It was true that the "works" when executed were to remain the property of the contractors, but an option of purchase was given to the Commissioners. It was not merely a contract to supply electricity but it was a contract to execute "works" in respect of which there was a detailed specification, from which no deviation was to be permitted. His submission was that the Commissioners were authorised to enter into this contract by virtue of Section 33 of the Act. The learned counsel submitted that the proposition which had been argued, that a person who took the whole of the profits obtained under a contract as a shareholder of the company was not a person who was directly or indirectly interested in the company, was scarcely worth replying to.

Mr. DANCKWERTS, Q.C., said he would like to put right a statement made by Mr. Cripps in his opening. Mr. Cripps had stated that it was not until after the action before Mr. Justice Kekewich was decided that the Corporation raised this question of the validity of the contracts. That was not so, because the question of the validity had been raised in the Council before that decision was given. The Act under which the Corporation were proceeding provided that no commissioner of sewers or alderman or common councilman should be "interested directly or indirectly" in any contract made with the Commissioners or the Corporation. "Interested" could only mean having a share of the profit or the loss, as the case might be, made upon the contract, and therefore every shareholder was "interested" in this contract.

At the close of the hearing, his lordship reserved judgment till yesterday (Thursday).

JUDGMENT.

Yesterday (Thursday) Mr. Justice Farwell delivered judgment in this action.

His LORDSHIP said that the present question arose on the construction of the City of London Sewers Acts of 1848 and 1851, in which it was set forth that no person being a commissioner should be, directly or indirectly, interested in any contract entered into with the commissioners, otherwise the contract would be null and void and the commissioner committing the offence would be liable in a penalty of £100 for each offence. It was admitted that at the date of the contract some commissioners were shareholders in the company. The Court could not set aside an Act of Parliament, even although its application might involve hardship; but if there were two possible constructions, then the Court might adopt the more reasonable of the two. In his opinion the Acts contemplated contracts of two sorts—construction contracts and contracts for supply of, say, water, gas, or otherwise. In his lordship's opinion the distinction between power to enter into construction contracts and the power to contract for the supply of light or water was reasonably plain. But it had been said that the contracts in this case contained clauses which made them construction contracts. In his lordship's opinion that was not so. The powers were given by provisional orders under certain electric lighting acts. The works connected with the supply remained the property of the plaintiff company, and the contracts were not construction contracts within the meaning of the Sewers Act of 1848. As to a commissioner being "interested," the Act of 1851 provided that no person being a commissioner, who was a shareholder in a lighting company, should be eligible to sit or vote as a commissioner while such a contract was under discussion by the commissioners; but to say that because a commissioner was a shareholder, and therefore that the contract was null and void *ab initio*, would be unreasonable. The commissioners were 91 in number and the common council numbered more, and that argument might mean that if one of them had held a single share in a gas company the contract with that company might at any moment be voided, and the result might be the absolute prohibition of the use of gas or electric light in the City. Again, assume that a company had spent a large sum in supplying the City with electric light, and it was subsequently discovered that one councilman had had a single share should the whole contract be void? As there were two alternative constructions capable of being put upon the Acts, he adopted the reasonable one, and made the declaration asked for by the plaintiff company that the contracts were good. The defendants would be ordered to pay the costs of the action.

Jandus Arc Lamp and Electric Co. (Ltd.) v. Johnson.

This was an action heard before Mr. Justice Farwell in the Chancery Division on Friday last on an application of the defendant.

Mr. GRAY (for defendant) said this was a summons for leave to amend the defence. The action was brought for payment of royalties under a licence, and the defence alleged that there were certain misrepresentations in the licence which destroyed the consideration that the defendant got under it. The defendant since Easter had discovered other misrepresentations, and he desired to amend the defence accordingly.

Mr. Graham (for plaintiff) did not oppose.

Mr. GRAY said he had also to ask for discovery. The defendant alleged that certain licences had been granted to others on better terms than had been granted to him. He therefore wanted to see all the licences which plaintiffs had granted as they had guaranteed to him that they had given him the best terms, but he had discovered one which was better, and there might be others.

Mr. GRAHAM said he would make an affidavit.

His LORDSHIP said it might be that the licences were not all in the same form, and the defendant would be entitled to see them all so that he might choose the best. The plaintiffs had better therefore make the affidavit, and the costs of this application be paid by the defendant.

Frankenburg v. David Moseley and Sons.

This case was in the list for hearing before Mr. Justice Farwell in the Chancery Division yesterday (Thursday), and was an action brought by plaintiff to restrain the defendants, by injunction, from infringing plaintiff's patent relating to improvements in the manufacture of indiarubber. The defence, among other things, was a denial of the infringement.

Upon the case being called on, Mr. Fletcher Moulton, Q.C., stated that the parties had come to terms, and the action would be withdrawn on terms, with his Lordship's consent.

His Lordship assented, and the action was accordingly withdrawn on terms which were not stated.

National Telephone Co. v. Tunbridge Wells Corporation.

The Tunbridge Wells Corporation have decided to apply to the High Court for a writ of prohibition in this case (particulars of which were given in our issues of March 23 and April 26) to prohibit Judge Emden from further dealing with the matter.

Workmen's Compensation.

In the course of an action heard before Judge Gye at Basingstoke County Court, under the Workmen's Compensation Act, an important point was raised as to the position of insurance companies. Plaintiff was a labourer named Penfold, defendant a builder named Tarrant. Defendant was nominally represented by Mr J. A. Kingdon, a solicitor, who, however,

Digitized by Google

in the course of the proceedings, clearly represented not the actual defendant, but the General Accident Assurance Co., of Perth, N.B., with whom defendant had insured his risk under the Act. In the course of the proceedings a receipt in full discharge to the agent of the insurance company was put in. Judge Gye asked if the defendant was willing to pay any reasonable amount apart from the insurance company's payment. The reply was that he was willing to pay reasonable compensation, but the insurance company had obtained a receipt in full from the plaintiff, and had taken the matter out of his hands altogether. Judge Gye said this was exactly what he had anticipated: it was the insurance company who were fighting the action. The evidence showed that the plaintiff had agreed with defendant that 11s. 6d. per week was reasonable compensation, and subsequently the agent of the insurance company induced plaintiff to obtain from his medical attendant a document showing the length of time he was likely to be unable to work. This document gave the period as four weeks, and a sum covering this period was paid by the company and a receipt in total discharge promptly secured. At the expiry of the four weeks it was found that plaintiff was unable to return to his employment, and a certificate to this effect was sent to the insurance company, with the result that the receipt in full discharge was put in as a bar to any further payment. During the evidence, Mr. Kingdon (the solicitor) attempted to cross-examine the witnesses, but Judge Gye peremptorily refused to hear him, and decided that he would not allow the intervention of the insurance company. The plaintiff was entitled (he declared) to claim compensation from his employer, the defendant, and it was, therefore, for these parties to the action to decide the points in dispute. There was, added Judge Gye, no place in the Act for the insurance company, nor had the Act contemplated any such parties' intervention. It will, of course, be observed that the Judges' objection was not to the act of insurance, but to the attempted transfer of plaintiff's right to sue his employer for compensation.

At the first hearing the case was adjourned to enable defendant to obtain legal advice, and on its resumption Mr. Temple Cooke appeared on defendant's behalf, and said it was important that the case should be defended, or otherwise the insurance company might dispute the policy.

Judge GYE said he had nothing to do with this point. He had only to deal with the case as between plaintiff and defendant, and he could not allow any insurance company to intervene. He had not taken this course without due consideration, but he found over and over again that the "undertaker" was willing to pay, but that the insurance company refused, and by this course were endeavouring to defeat the aims and ends of the Workmen's Compensation Act. In the present case a most disgraceful defence had been put forward on behalf of the insurance company.

Mr. TEMPLE COOKE said the term "Compensation Act" was a misnomer. It was really an Insurance Act.

Judge GYE: Nothing of the sort. The insurance companies have stepped in as they do everywhere. He was not prepared to allow them to step in by a crooked path.

Mr. TEMPLE COOKE said the practical result of his honour's ruling was that no employer would insure against accident to his employees.

Judge GYE said that in the Act there was no mention of insurance companies; only the word "undertaker" was mentioned, and the "undertaker" must fight it out with the insurance company separately. If the insurance company wished to fight the matter they must do it on appeal.

Mr. TEMPLE COOKE then assured his honour that he appeared for the defendant, and not for the insurance company.

Judge GYE: If that is the case, it would be dangerous for me to disallow you to appear.

In the course of the evidence which followed, the receipt was again put in, and purported to be a receipt in full discharge of all claims made, or to be made, under the Workmen's Compensation Act, 1897, the Employers' Liability Act, 1880, or at common law. A consultation took place between Counsel with a view of settling the case, but Judge Gye stated that he would not agree to any settlement of the action.

Mr. TEMPLE COOKE said he was not aware that it was necessary to get the consent of the Bench to a settlement in an action of this character.

Judge GYE replied that there had already been a settlement, which was repudiated.

At the conclusion of the evidence, Mr. TEMPLE COOKE submitted that the defendant was justified in defending this action; otherwise, if he went to the insurance company and claimed further payment to his workmen under the policy the company might say he had not troubled to dispute this matter. On the faith of the doctor's certificate, the company were justified in taking the course they had done. It was true they had snatched this settlement from plaintiff, but they were a commercial body and wished to make the best they could out of it. If it were not for the insurance companies where would the employers be under the Act?

Judge GYE: You have summed up the case neatly. But the insurance companies make a really good thing out of this business.

His HONOUR in giving judgment said it was clear plaintiff was entitled to further compensation. The very point raised in this case was one which he had expected would be raised ever since the Act came into operation, and he was surprised it had not been raised before. The object of the Act, he understood, was that a workman should be entitled to receive compensation from his employer for any injury he might receive in the course of his employment. The legislator had removed a large number of restrictions and legal defences from the operation of the law as it stood before this Act was passed, and it was provided that, broadly speaking, unless the workman brought about the accident by his own wilful misconduct he should be able to recover from his employer damages for any injury happening under any of the circumstances specified and enumerated in the Act. It was intended by the Act that a workman thus injured should, during the period he was incapacitated, receive the means of livelihood. Further than that, it was intended by the Act—a point in which it had lamentably failed—that the workman should be enabled to conduct the proceedings for arbitration without professional assistance, and that workmen meeting with a variety of small injuries should not be obliged to go to a solicitor and incur costs. It was, in short, intended to put the matter as much as possible in the man's own hands. But the unfortunate technicalities and complications of the Act had rendered it absolutely impossible, in a great many cases, that a man of even more than ordinary intelligence could find out what the Act meant on this or that point. That difficulty had been considerably enhanced by the intervention of the insurance companies. They, being commercial concerns, issue policies to employers to cover all those accidents and risks, a state of things, he ventured to think, that was never contemplated by the legislature when the Act was passed. The effect of that intervention on the part of the insurance companies and of the universal desire to insure liabilities on the part of employers had been that, when from motives of honest and kindly feeling an employer was only too willing to compensate a man for injury, the insurance company stepped in and said "we shall fight this." The result was that an extraordinary number of cases were fought by the insurance companies for their own purposes, and they endeavoured to keep from the workman that compensation which his employer was willing and desirous he should receive. The sole end and aim of the insurance companies was to get rid of the liability, and the workman stood the risk of being deprived of compensation, not by the wish of the employer, but by the sole consideration of £. s. d. by the insurance companies. The Act was difficult enough to administer when both sides were willing for arbitration; but it was almost impossible to administer it when every little point was taken by counsel or solicitor to defeat the claim of the applicant. The Act itself bristled with difficulties; little wonder, then, that the insurance companies gladly fastened on the difficulties, and endeavoured to defeat these claims. It was a rich harvest for them. He (Judge Gye) had no hesitation in saying that if a receipt such as had been put in in this case had been obtained over an ordinary action for a money claim, and the plea had been put forward that the signatory did not know what he was signing, an action for fraud would be successful. If such procedure were allowed to go on it would put an end to honest dealing between workmen and employers. A great deal of injury to both was undoubtedly done by this busy intervention on the part of insurance companies. The balance due to plaintiff was £8. 1s. 6d., and he gave judgment for that amount, with costs.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Arcona.—At Arcona, the northern point of the island of Rgen, a new lighthouse is being erected at a cost of £11,823. The light adopted is an electric flash light of one-tenth second duration at intervals of $4\frac{9}{10}$ seconds. The light will be visible 22 miles.

Atlantic Cable Enterprise.—According to a telegram published in the Paris edition of the *New York Herald*, a company is to be formed (under a charter to be obtained from the State of New Jersey), to be called the American-European Cable Co., with a capital stock of $10,000,000, the bulk of which, it is stated, has been subscribed. Mr. W. H. Worl and a number of capitalists are said to be behind the company, which proposes to lay a cable from New York to Portugal, under what is described as "a right ceded in 1867 to the American Atlantic Cable Co. by special Act of Congress to lay cables on the Atlantic Coast of the United States without conditions or restrictions."

Birkenhead.—During the past year 238,546 units of electric current were supplied to 215 consumers, compared with 169,676 units and 158 customers in 1899.

Birmingham.—The City Council on Tuesday adopted the recommendation of the Public Works committee to authorise the City of Birmingham Tramways Co. to equip the Bristol-road tramway route on the overhead trolley system. At present the accumulator system is employed.

Blackpool.—The receipts of the electric tramway department to March 31 amounted to £22,570, compared with £18,196 in 1899. The number of passengers carried was 3,421,730, compared with 2,881,027, and the distance covered 318,885 miles, against 259,754. Various extensions of the lines are being carried out.

Bootle.—Differences have arisen between the Council and the Liverpool Corporation in regard to the running of through trams. The chairman of the Highways committee (Councillor Hall) announced on Wednesday that further communication had passed between the committee and the Liverpool Tramways committee, but a settlement had not been arrived at. The matter had been referred to the Board of Trade. The committee contended that the responsibility for the electric cars not being yet placed on the Bootle lines rested with the Liverpool Corporation.

Bristol.—The Local Government Board have sanctioned the borrowing of £145,150 for electric lighting extensions. The period of the loan is 25 years. An application from the Mangotsfield Parish Council for a supply of current has been refused.

British Fire Prevention Committee.—Vols. II. and III. of the publications of the British Fire Prevention committee, advance copies of which we have received, contain among other matter a description of the testing station of the committee and accounts of tests with unprotected columns, floors, ceilings, glass, doors and

Digitized by Google

partitions. A reprint of a Paper on "Conflagrations During the Last Ten Years," read by Mr. C. E. Goad before the Insurance Institute of Manchester, will also be read with interest in view of the recent disastrous fire in Ottawa, and of the Charity Bazaar Fire in Paris, of which to-day is the anniversary. The publications are edited by Mr. Edwin O. Sachs.

Brussels-Antwerp Electric Railway.—The Bill for the construction of the proposed line has been defeated in the Committee of the Belgian Chamber.

Canada.—The electrical industry in Canada is, according to recent reports, participating fully in the prosperity which is a feature of the time. The leading electrical manufacturing and supply companies report that the volume of business for 1899 exceeded that for 1898 by upwards of 75 per cent., and this notwithstanding that only comparatively small additions have been made in the form of new undertakings. Progress has been shown in the substitution of up-to-date plant for that previously in use, and in very considerable extensions and improvements to existing lighting and power undertakings. The market quotations for stocks and shares in electric joint stock concerns in the Dominion show a marked rise, and further advances are confidently predicted. The utilisation of water power for the generation of electric current is being taken up with great energy, and cheapened production is resulting in largely increased demands for electric enterprise throughout the country.

Cardiff.—A meeting of the Electric Lighting committee was held on Tuesday to consider a report from the borough electrical engineer (Mr. N. Appelbee) on the electrical undertaking, and particularly as to the advisability of erecting new electricity works for supplying electric current for lighting and traction. Mr. Appelbee recommended that he be instructed to prepare detailed plans and estimates for the proposed works, and that application be made for borrowing powers; that trials should be made with inferior grades of fuel, using induced or forced draught; that the coal elevator and conveyor scheme as originally arranged should be carried out; that Messrs. Siemens Bros. and Co. be asked to give a quotation for a 500 H.P. steam alternator, and Messrs. Babcock and Wilcox for an additional boiler; that the equivalent of 500 H.P. in transformers be obtained; and that two additional feeder cables from the works to the centre of the town be laid at once. Mr. Hallett thought that forced draught would not be advisable, and the electrical engineer did not press the point, so this portion was struck out. It was stated that the present plant would only carry the department over the coming winter. The committee deferred considering the recommendations to enable Mr. Appelbee to draw up a further report, particularly upon the advisability of at once considering the necessity of providing a new generating station.

"Carols from Car."—Mr. Geo. M. Baines, accountant at the Eastern Telegraph Co.'s station at Carcavellos, Portugal, is as well known in this charming district for his poetry and music as for his skill in the profession of which he is a respected member. In a volume of carols just published Mr. Baines tempts the muse in many strains, from the lullaby of the sunny south (*à la* Eugene Stratton) to the more ambitious sonnet and serenade. The introduction of "service" technicalities into some of the verses is very neatly accomplished, and will raise many a smile. Here and there a carol deals with local subjects, and Mr. Baines' residence for some years at Fayal, in the Azores, as superintendent when the cable was first laid to that island, affords him the opportunity of expressing in trenchant verse his longing to return to the home of his choice—Carcavellos. This regard for "Car.," where men in the service of the Eastern and associated companies spend so many pleasant days, is very general, and fully excuses Mr. Baines for devoting many of his carols to the glorification of the Mecca of at any rate the younger members of the submarine cable services to the East and West. The book has been nicely printed in Lisbon and is frontispieced by a photograph of the exterior front of the Carcavellos station, an old Portuguese baronial house of bold design, charmingly situated.

"Cassier's Magazine."—The May issue includes articles on "Electric Riveting Machinery," "Electric Central Stations and Isolated Plants," "Systematic Piece-work Pricing," and "Typical Horizontal British Steam Engines."

Central London Railway.—Mr. D. J. Ross, engineer to the City of London has been given permission by the Corporation to accept a gratuity of £1,050, for services in connection with the Bank station and subways of the Central London Railway.

Country House Lighting.—Gayhurst House, Bucks, the residence of Mr. W. W. Carlile, M.P., has been provided with a very complete electric lighting installation. The work was entrusted to Mr. R. F. Yorke, M.I.E.E., of Glasgow, and under his supervision was carried out by Messrs. G. and W. Simpson. 280 lamps have been installed. Current is supplied by a Laurence Scott shunt-wound dynamo, driven by a 12 H.P. Hornsby oil engine, with a 6in. Hendry's patent laminated belt, and in addition there is a battery of 66 Chloride cells. The stables and outbuildings are also lighted electrically.

County Councils and Electrical Undertakings.—A deputation from the County Councils Association and other bodies waited upon the Board of Trade last week, to obtain Government support for the bill exempting County Councils from responsibility for damage to electrical communication through the necessary widening and repairs of bridges. In reply, the President (Mr. Ritchie) said the principle contended for by the deputation appeared to be a reasonable one, although objection might be taken to its being retrospective. It was rather a strong order to say, when Acts of Parliament and provisional orders had been obtained by electric lighting undertakings under the protection of the existing law, that they should now be made liable under this bill to expenses to which they were not previously liable. The bill, which was very defective, had a most unfavourable position in the House, and he suggested that it would be better if it were withdrawn and reintroduced in an amended form. The position of electric lighting was not what it was in 1882, and he thought the deputation's case would be stronger if they went to Parliament, and asked for a reconsideration of the position in which local authorities were placed in connection with such expenses.

Customs Duties.—Under the new Spanish tariff every description of electrical and scientific apparatus and instruments is classed under a heavy rate, and is plus a 20 per cent. war tax.

Under the new customs tariff of Paraguay telegraph wire, steam engines and fittings, calcium carbide and scientific instruments are admitted free.

Dinner.—The fortieth annual dinner of the old students of King's College, London, will be held at the Holborn Restaurant on Monday, June 18, when the Hon. Sir John Alexander Cockburn, K.C.M.G., Agent-General for and formerly Premier of South Australia, will preside. His Royal Highness the Duke of Cambridge has notified his intention to be present. Students can obtain all information of Mr. W. Vincent at the college.

Dock Lighting.—The Mersey Docks and Harbour Board have decided to light the Birkenhead foreign animals wharf electrically. The Woodside portion has for some time past been so lighted, current being supplied by the Birkenhead Corporation; but the board have now decided to put down an independent plant.

East London Technical College.—Mr. J. T. Morris will give a special course of six lectures on "Electric Lighting and Power Stations," on Thursday evenings, commencing 17th inst., and a course of eight lectures on "Three-phase Currents," on Tuesday evenings, commencing 8th inst. Some particulars are given in an advertisement, and further information can be obtained from the director of studies (Mr. J. L. S. Hatton, M.A.), People's Palace, London, E.

Eastbourne.—An important report by Mr. W. C. C. Hawtayne on the position of the electricity undertaking was considered by the Council yesterday (Thursday). Mr. Hawtayne states that as the company's undertaking was commenced in 1882, some of the machinery is old and very inefficient, and recommends the Council to instal a direct complete set capable of developing 400 kw., and an additional boiler, the cost of the new plant being £5,050. The re-modelling of the mains was the most important matter. In regard to the transforming of the high-pressure current for private supply, Mr. Hawtayne points out that the duration of the maximum load was only about 1 to 2 hours per day, so that for approximately 22 hours out of 24 a considerable amount of energy was being wasted, and that waste could only be checked by getting rid of as many of the small transformers as possible, and substituting for the present system of distribution a proper low-pressure system of mains fed at intervals by large transformers grouped in sub-stations. The alterations suggested should bring down the losses from the inefficiency of the present system to about 15 per cent. of the units sold, against about 60 per cent. The change of pressure would enable them to take twice as many consumers on the low pressure mains, while also halving the losses in distribution. The cost of the alteration would be approximately £10,700. The present house service fuses and meters would also partly require replacing, involving a further cost of about £4,000. The 25 public arc lamps on the sea front running in series off the old Brush machines should be connected up to the low-tension distributing network, and would therefore require to be altered, or preferably replaced by lamps of a later type, at a cost of about £260. If the Corporation proposed to extend the arc lighting to certain additional thoroughfares named in the report, 38 additional arc lamps would be required, and the capital outlay would be about £1,500. Those lamps would replace about 33 existing incandescent gas and 30 ordinary burner lamps, costing about £37 per annum, and if the Corporation decided upon a charge of £17 per 1,000 c.p. arc lamp per annum, the extra annual expenditure for arc lighting would be £409. The electric arc lamps would give about ten times more light than at present. The provision of a new switchboard would cost approximately £1,100. On the question of the site of the works, Mr. Hawtayne advised the construction of new works at Roselands in conjunction with the re-modelled refuse destructor and sewerage works. In any event, whether the electricity supply works are erected at Roselands or not, a considerable expense must shortly be incurred on buildings in order to place the existing works on a proper footing. The cost of

Digitized by Google

this work might amount to anything between £2,000 and £3,500, according as to whether or not a new shaft is required. The cost of buildings with a new chimney shaft for a combined scheme of lighting, sewerage, and destruction of refuse would be about £9,500. On the question of changing over from the alternating-current to the continuous-current system. It would not be possible to adopt the continuous-current system without considerable alteration to the whole of the cable network, and practically reopening the whole of the streets where cables were now laid. Lighting the remaining streets by incandescent electric lamps (997 16 c.p. and 53 32 c.p. lamps) would cost £17,450, and the total annual expenditure for maintenance, &c., is estimated at £4,231. The Electric Light committee recommend the Council to transfer the works to Roselands, and to instruct Mr. Hawtayne to prepare the necessary plans and specifications; that the borough engineer prepare the plans of the new building required, in consultation with Mr. Hawtayne; and that tenders be at once invited for the new main switchboard and 400 kw. steam alternator, with boiler. The total cost of the proposed works is estimated at £33,562. After discussion the Council yesterday (Thursday) decided to adopt Mr. Hawtayne's report and recommendations.

Edinburgh.—The Electric Lighting committee have issued their draft estimates for the year 1900-1901. The estimated expenditure, including £5,800 for rates and taxes, is £45,715, making, with £40,000 for sinking fund and interest, a total of £85,715, against £63,285 this year. The estimated revenue, after taking into account the proposed increase of ¼d. per unit on the present price of 3½d. for private lighting, in consequence of the rise in the price of coal, is £90,000, compared with £73,405 in the current year. The estimated capital expenditure in 1900-1901 for works at the Dewar place and M'Donald road stations, and the extensions of mains and cables, &c., is £113,450. The price for public lighting has been fixed at £13 per lamp per annum, a reduction of £1; the price for motor power is to remain at 1½d. per unit. The number of lamps applied for during the last fortnight was equal to 5,348 8 c.p. lamps, and includes 15 motors.

Edmonton (Middlesex).—At its last meeting it was resolved by the District Council that application be made for an electric lighting provisional order.

Electric Traction in Spain.—A Royal order was recently issued authorising the construction of electric tramways in Almeria and the vicinity.

Engineering Education.—Instruction is given in civil, mechanical and electrical engineering at the Hertfordshire Training School of Engineering, and some particulars are set out in an advertisement.

Factory and Workshops Bill.—This bill, now before Parliament, if passed as it stands, is calculated to considerably increase the liability of occupiers of factory premises in the provision of means of escape in case of fire, and the Manufacturers' Section of the London Chamber of Commerce suggests various amendments to the bill, and particularly to sec. 15, which deals with the means of escape to be provided. It appears that under the Act the occupier of any factory erected since Jan. 1, 1892, or of any workshop erected since Jan. 1, 1896, in which more than 40 persons are employed, must, if situate in the area over which the London County Council has control, be furnished with a certificate from the Council that reasonable provision has been made for escape in case of fire of all persons employed above the ground floor, or otherwise the upper floors must not be occupied. It is pointed out that the bill proposes to give the Council the same power for old as for new factories and workshops, *i.e.*, the power to decide whether a factory or workshop may continue to be used or not. The London Chamber of Commerce calls the attention of factory owners to the clauses of this bill. Copies of the suggested amendments can be obtained on application to the secretary, Mr. K. B. Murray, Botolph House, Eastcheap, E.C.

Gravesend.—Mr. W. H. Trentham is to attend the next meeting of the Electric Lighting committee to discuss the question of the erection of electricity works.

Hales Owen.—Acting on the advice of Mr. R. P. Wilson, the District Council have resolved not to dispose of their electric lighting order until they have obtained a tramway provisional order, which will be applied for next session.

Leeds.—The salary of the mains superintendent has been increased from £208 to £230, with a further increase to £250 at the end of twelve months.

Leicester.—A sub-committee has been appointed to visit Paris, Brussels, Berlin, and Budapest, in order to report to the Council upon the systems of electric traction in operation in those towns.

Leith.—The burgh electrical engineer (Mr. W. A. Bryson) has tendered his resignation, as he intends to confine himself to consulting work. The Council are advertising for Mr. Bryson's successor in another column.

Limerick.—Progress is being made with the electric lighting scheme, the plans of which have been approved by the Local Government Board. The consulting engineer is Mr. J. Enright.

Lymington.—The Lymington Electric and Power Co. are commencing the work of erecting their electricity supply station.

Maidenhead.—The Council have decided to apply for sanction to a loan of £25,000 for electric lighting.

Manchester.—At the Corporation meeting on Wednesday, the estimates for the ensuing year were presented by the Finance committee and approved. Last year the Electricity committee contributed £10,000 to the relief of rates, but this year the contribution will be nil. The Gas committee's contribution has been reduced from £52,000 to £20,000. In reply to questions Ald. Higginbottom said the engineer had withheld the supply from Cheetham Hill because he could not, with the existing plant, have maintained the voltage required. The mains were being prepared for tramway and lighting, and they would be carried to Cheetham first. The Electricity committee had handed over £68,000 to the City Fund, and had built up a reserve fund of £40,000 out of the profits, and yet they were told they might have been in bankruptcy because they did not feel justified in handing over £10,000 or £20,000 to the City Fund. The mains were laid down under the best advice in the country. It had been found, however, that the damp climate of Manchester would not allow the indiarubber cables to "live" there. It was only those cables which had proved defective, and he did not think they would have any trouble from any of the cables with which they had been replaced. With regard to explosions, Manchester was not worse off than other places. The extension to outside districts was carried out in accordance with the policy of providing electric tramways and lighting for the out-districts.

Marylebone (London).—The Parliametary committee has been instructed by the Vestry to take the necessary steps to oppose in all its stages the bill for confirming the provisional order to the Marylebone Electric Supply Co.

Newcastle-on-Tyne.—An inquiry was held on Tuesday by Mr. A. P. Trotter into the application of the Corporation to borrow moneys for electric tramways. The town clerk (Mr. Hill Motum) and the consulting engineer (Mr. C. Hopkinson) supported the application. Provisional contracts have already been let, and Mr. Motum said the Corporation had authority to construct 20 miles of double tramways and to work them electrically. The tramways were in course of construction, and about 11 miles were at present being proceeded with. They proposed shortly to invite tenders for the remainder. He asked that as long a time as possible should be allowed for repayment of loan. Mr. Trotter said that the usual terms were 50 years for buildings, 20 years for electrical equipment, and 15 years for cars, and sometimes an average was struck. The Corporation asked for 50 years for the buildings loan, but that was an unusual time, and he was afraid it was not possible under the Tramways Act. The town clerk submitted that the application was not made under the Tramways Act, but under the Local Act of last year. Mr. C. Hopkinson gave technical particulars. The power station, he said, was being built larger than was immediately required so that there might be provision for extensions. They were going to have 100 cars built at present. The gradient would be about 1 in 13. The brake to be used would be a mechanical brake, but they were arranging the cars so that they could add a further brake to the bogey cars. There was no opposition.

Mr. Cail, chairman of the Tramways committee, has been commissioned to pay a visit to the German Steel Works, in Westphalia, to make an expert inspection of the next delivery of 600 tons of tram rails on behalf of the Corporation. If necessary, Mr. Hopkinson, the electrical engineer, is to accompany Mr. Cail.

Norwich.—The new Technical Institute has been provided with an electric lighting installation by Messrs. G. N. C. Mann and Co. There are about 800 lights.

Police.—At the Marylebone (London) Police Court on Wednesday, a youth named Toye was charged with loitering in the Harrow-road for the supposed purpose of committing a felony, and further with inciting David Catherall and Walter Gower to steal. Prisoner had been in the employ of Messrs. Evershed and Vignoles, electrical engineers, Woodfield Works, Harrow-road, W., and was discharged two months ago. Catherall, who was called as a witness for the prosecution, gave details of his connection with the prisoner, who apparently had arranged a plan for obtaining possession of the cash bag of Messrs. Evershed and Vignoles' cashier, but the plan failed as the cashier did not return by the usual route. The magistrate (Mr. Curtis Bennett) complimented the two witnesses, Catherall and Gower on their conduct and rewarded them for their loss of time. Prisoner was sentenced to three months' hard labour.

At West Ham on Friday, Charles Maddock, wireman, was again charged with attempting to set fire to a building at Factory-road, Silvertown, the property of the Indiarubber, Gutta Percha and Telegraph Works Co. Particulars of this case were given in our last issue. After taking further evidence the magistrate committed the prisoner for trial to the next sessions of the Central Criminal Court.

Prague (Bohemia).—In a report on the trade of Bohemia, just published, it is stated that an excellent service of electric tramways now runs through the principal thoroughfares of the city. Prague is well lighted by electricity, the municipality being the owners of the undertaking. Public and private supply is generally adopted. The telephone service, which was originally established by an English company, is excellent, and the city is in direct communication with Vienna, Berlin, Dresden, and other important Continental cities. The telephone service is owned by the Imperial Government.

Plymouth.—There was a net profit of £298 on the Corporation tramway undertaking last year. The adverse balance, due to the accumulated deficits of previous years, stood on March 31, 1899, at £8,659. The actual deficit of the previous year was £1,321, so that the accounts of the year just closed show a total gain as compared with 1898 9 of about £1,600.

Personal.—A marriage has been arranged, and will take place at Brighton, on July 7, between the eldest daughter of the mayor of Brighton (Ald. J. E. Stafford) and Mr. W. C. P. Tapper, resident electrical engineer at the Whitechapel (London) electricity works.

Presentation.—On 28th ult, the employés of the Brush Co. assembled in one of the new shops at Loughborough to present a testimonial to Mr. C. E. Hodgkin on the occasion of his retirement from the post of works manager. The presentation, which consisted of a bacteriological microscope and lamp, chemical balance and weights, 10 power Ross binocular and an album containing the signatures of the subscribers, was made by Mr. F. E. Andrews, the works secretary, supported by Mr. Councillor Yeomans. Mr. Hodgkin suitably acknowledged the present.

Private Bill Legislation.—The Liverpool Overhead Railway Co. propose to apply for leave to introduce clauses in their bill empowering them, with the consent of the Mersey Dock and Harbour Board, to equip the Mersey dock railway electrically.

The Dublin Electric Lighting Billwas read a second time in the House of Commons on Monday.

The Vale of Rheidol Light Railway bill has passed through the committee stage of the House of Commons, and has been ordered for third reading.

Opposition to the Preston Corporation's Tramway and Extension bill has been withdrawn.

Of the 19 petitions originally lodged against the London United Tramways (Extensions) Bill only one (by frontagers in the Richmond-road, Twickenham) remains. The bill will be considered by a House of Commons committee, under the chairmanship of Sir U. Kay Shuttleworth.

The Standing Orders committee of the House of Commons have allowed the Glasgow District Tramways bill to proceed, but the tramways on the north side of the Clyde, with the exception of those projected in Dumbarton, have been struck out.

Rhyl.—An inquiry was held last week into the application of the Council to borrow £37,000 for electric lighting, refuse destructor and other works. The clerk (Mr. A. Rowlands) said the Council anticipated making a substantial profit on the first year's working, as an agreement had been entered into with the Rhyl and Prestatyn Light Railway Co. to supply electrical energy for their tramway, at a profit of over £400 per annum. It was intended to supply current to private consumers at 6d. per unit.

Ruthin (Denbigh).—A special meeting of the Council is to be held to consider the advisability of applying for electric lighting powers.

St. Helens.—The Electric committee recommended at the Council meeting on Wednesday that the salary of the borough electrical engineer (Mr. J. S. Highfield) be increased from £300 to £500 per annum. It was explained that Mr. Highfield was first appointed in 1898 at a salary of £200, and in July, 1899, he had the option of accepting another position at a salary of £500 per annum. The committee gave him a bonus of £100, and promised that if he would not leave until the electrical equipment of the tramways was completed, he should have £500. Notwithstanding this promise, an amendment was carried that Mr. Highfield's salary be only increased to £400. The salary of the assistant electrical engineer (Mr. E. M. Hollingworth) has been increased from £110 to £150, and the salaries of Messrs. G. H. Carter and E. E. Eccles. shift engineers, from £100 to £125.

St. Pancras (London).—The Vestry have sanctioned an expenditure of £3,000 for laying a new feeder for the Seymour-street district, with an ultimate extension to Somers Town. The outlay includes cost of distributing and arc lighting mains in Ampthill-square and Bedford-street. A proposal by the Electricity committee to reduce the charge for current to churches, chapels, and hospitals from 5d. to 3d. per unit as from July 1 next was referred back. The chairman (Dr. W. Smith) said that there were 65 churches and chapels in St. Pancras, of which only 12 were supplied with current by the Vestry, but if the proposed alteration was made he believed they would be able to induce all to become customers.

Salford.—A special meeting of the Corporation will be held on Monday to consider the report of the Electric Light committee relating to the resignation of the late chairman, Councillor Haworth and the matters connected therewith.

Scarborough.—The Corporation are negotiating for the purchase of the undertaking of the Scarborough Electric Supply Co. (Ltd), and the company intimate that they are prepared to sell "on the basis of the present and prospective value." The committee having charge of the negotiations offer to buy at a valuation to be fixed by an arbitrator.

Shoreditch (London).—The electrical engineer (Mr. C. N. Russell) has been unable to recommend the acceptance of either of the two tenders received for the supply of four 165 kw. transformers, and the Vestry have decided to invite fresh tenders, and to permit makers to offer their largest size of transformers suitable for the purpose. One of the original tenders was not according to specification, and the price of the other was considered to be too high.

Stafford.—During the past year the electricity department generated 118,341 units of electric current, an increase of 27,207 over last year. The department is in negotiation with Mr. W. O. Rooper for an annual supply of about 100,000 units for works lighting and motor driving.

Stettin (Germany).—The total length of electric tramway lines belonging to the Stettin Electric Street Tram Co., opened to traffic at the end of 1899, was 44,373 metres (about 27½ miles). The company's rolling stock consists of 82 motor cars, 22 closed and 21 open cars, one snow-clearing car, and four salt-strewing cars. The net profits for 1899 reached £9,376, and the company paid a dividend of 6 per cent. The overhead electric trolley system is now in operation over all the lines.

Stores Lighting.—The extensive range of shops occupied by the Bon Marché Co., at Stoke Newington, London, are to be lighted throughout electrically. Jandus arc lamps are to be used for the interior lighting, and Crompton-Pochin open type for the exterior. An independent gas-driven generating plant is being installed. The consulting engineers are Messrs. Taylor and Field.

Sunderland.—According to the report of the electrical engineer (Mr. John F. C. Snell) the profit on the electricity undertaking during the past year amounted to over £1,000, of which £700 has been applied to reduction of rates.

Telephone Wayleave Charges at Newcastle-on-Tyne.—A committee has been considering the advisability of charging a rental for underground telephone wayleaves to the Post Office and the National Telephone Co. The Post Office authorities requdiate any liability to such a charge. The committee recommend that no charge be imposed on existing renters, but that, in the case of all new subscribers, the charge be at the rate of 2s. 6d. per renter under both telephonic services.

Telephone Wayleaves.—The summons against the National Telephone Co. for opening up the pavement in Marshalsea-road, Borough, for the purpose of laying down telephone conduits and wires without the usual notice, has been withdrawn by the Vestry of St. George the Martyr (Southwark). At the police court on Tuesday the vestry clerk (Mr. Johnson) stated that the company had admitted that the wires were laid without authority, and agreed to pay £10 per annum in consideration of the wires being underground.

The War in South Africa.—The outbreak of hostilities in South Africa and the extension of the period during which these hostilities are likely to continue, has led to large imports of electric machinery and material into Cape Colony, Natal, and other South African ports, which in October, 1899, exceeded those for October, 1893, by £6,000. Reports to hand show that this increase continues a feature in South African imports.

Water-power Utilisation in India.—The Government of India are willing to receive proposals for lighting Wellington by electricity, generated by water-power from the Karteki Falls, in connection with the scheme for the utilisation of water-power from the falls for the cordite factory which is being built in the Arvenghat valley, Nilgiris.

Water-power Utilisation in Spain.—The Sociedad General de Centrales Electricas, Bilbao, has secured the concession for utilising the water-power of the river Leizaran, near Andvain (Guipuzcoa). It is estimated that 2,800 H P. will be available.

West Australia.—At the meeting of the Colonial Consolidated Finance Corporation, on Wednesday, the chairman said they had decided to participate in the proposed scheme for the construction of an electric tramway at Kalgoorlie, and now held a quarter-share in the tramways concession. The intention was to build the tramway without appeal to the public. They were told by the engineers who built the Perth tramways that the Kalgoorlie lines would be a better paying scheme than Perth. They expected to commence constructing at Kalgoorlie at once, and hoped to have some part of the tramway open for traffic towards the end of the year.

Digitized by Google

West Bromwich.—An inquiry has been held into the application of the Corporation for sanction to borrow £30,000 for erecting electricity works. There was no opposition.

Weymouth.—The Council have considered and adopted a report by Prof. A. B. W. Kennedy recommending the erection of electricity works, at an estimated cost of £38,300. Application has been made to the Local Government Board for sanction to borrow £42,000 for covering the cost.

Wireless Telegraphy in Germany.—A company, entitled Braunsche Telegraphen Gesellschaft, has been formed in Hamburg with a capital of 2,000,000 marks (£100,000) for the purpose of continuing the experiments of Prof. Braun, of Strasburg, in wireless telegraphy, the exploitation of his patents, and the establishment of complete installations of wave telegraphy on land and sea. The company takes over an agreement made between the Schuckert Co. and the syndicate hitherto dealing with the Braun patents.

Worcester.—In order to encourage the demand for electric current, the Council have decided to ask the Local Government Board to sanction a loan of £1,000 for wiring consumers' premises.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers, or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

READY.

(Price 12s. 6d., by post, 13s. 3d.; Colonies, 14s.; abroad, 14s. 6d. (United States, 15s.)

"The Electrician" Electrical Trades' Directory and Handbook for 1900.—In addition to the well-known features of this Directory and Handbook (all of which have been carefully revised and brought quite up to date) a large addition has been made to the Handbook Division, including a Digest of the Law of the Telegraph and Telephone, for the use of municipalities and companies contemplating applying to the Postmaster-General for a Telephone Licence. This section of the book now includes the new model form of Licence issued by the Postmaster-General, the Telegraph Acts and Orders passed by Parliament in 1899, and other information in connection with this the latest development of electrical enterprise. The huge sheet tables of Electric Light and Power and Electric Railway and Tramway undertakings of the United Kingdom have been made quite complete. These sheets form a most complete record of electrical engineering progress in connection with electricity supply and power and traction applications. The Directory Division has been carefully extended and corrected, and is the most reliable list of firms and persons engaged in the electrical and allied industries ever compiled. A number of additional sketches of the careers of well-known electrical experts have been added to the Biographical Division, together with many new portraits. The new volume is the most complete and correct book of its kind ever published in any language.

"The Electrician" Reading Case.—To hold four numbers of the journal. Strongly bound, 1s. net; post free, 1s. 4d.

"Magnetic Induction in Iron and other Metals."—By Prof. J. A. Ewing. Price 10s. 6d. net. *New Edition (Third) now ready.*

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free. The book deals with the important subject of localising faults in electric light and power cables; and the various methods of insulation testing are here collected and discussed.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves." A Review of the Work of Hertz and his Successors.—By Dr. O. J. Lodge, with a large number of illustrations, bringing this latest application of electrical science quite up to date. New and Enlarged Edition, 5s. nett. *Now ready.*

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free. The authors give in a clear and concise manner a good summary of the general principles of electrical science.

"The Incandescent Lamp and its Manufacture."—By Gilbert S. Ram. Price 7s. 6d., post free. The principles underlying the manufacture of the incandescent lamp are carefully and fully dealt with in this volume.

"The Centenary of the Electric Current, 1799-1899."—By Dr. J. A. Fleming. Price, paper covers, 1s. net, post free 1s. 3d.; strong cloth, s. 6d., post free.

"Motive Power and Gearing for Electrical Machinery."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free. In this comprehensive work an account is given of the scientific principles and modern practice in the use of engines for dynamo driving, not only for isolated power plants, but also for public electric lighting and power stations. The various forms of gearing in the power station and for electric motors are also dealt with; and the book contains, in addition, numerous tables giving exact data of the equipment and working of electric power stations.

"The Manufacture of Carbons for all Electrical Purposes."—by Francis Jehl. 10s. 6d., post free. This is a practical handbook, giving a complete description of the art of making carbons for electric lighting, electrodes, &c., with particulars of the various gas generators and furnaces used in carbonising. The work also contains particulars of the cost, &c. of erecting and working carbon works, and plans of a model factory.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. *New and Cheaper Edition*, 6s., post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free.

"Submarine Cable-Laying and Repairing.—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. This work gives a detailed technical summary of modern practice in manufacturing, laying, testing, and repairing submarine telegraph cables.

"Electromagnetic Theory."—By Oliver Heaviside. *Vol. I.*, 12s. 6d. *Vol. II.*, 12s. 6d.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free. The author treats fully both the theoretical principles of the art of electrolytic separation of metals and the practical rules and details of technical application on a commercial scale. The work is adapted to the use of the manufacturer as well as the student.

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d., post free. Propsectus on application. This is a complete treatise on the theory and construction of drum winding, and of commutators for closed coil-armatures, together with a *résumé* of the principal points involved in their design, and an exposition of armature reactions and sparking.

"Laboratory Notes and Forms."—We have ready a set of 40 Elementary and Advanced Exercises for use with Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of the series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnics and other Science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper, and with less space for tabulated records, are issued at half the price of the original set.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

The *Postmaster-General* invites applications for copies of the Post Office specification, and forms of tender for galvanised iron strand stay wire for telegraph purposes. Applications to the controller of stores (Mr. Chas. E. Stuart), G.P.O. West, London, E.C. See advertisement.

Glasgow Corporation require tenders for creosoted poles, oak arms, insulators, ironwork, and ironwork used in telephone construction. Specifications, &c., may be obtained from the telephone engineer (Mr. A. R. Bennett), City Chambers, and tenders must be lodged with the town clerk (Sir J. D. Marwick) by Wednesday, 16th inst. See advertisement.

Glasgow Corporation also require tenders for indiarubber-covered and lead-covered branch cables and carbons for one year. Specifications, &c., may be obtained from the engineer (Mr. W. A. Chamen), 75, Waterlow-street, Glasgow, and further particulars are given in an advertisement. Tenders to the town clerk (Sir J. D. Marwick) by 19th inst.

Leeds Lighting committee invite tenders for two or three 630 kw. two-phase generators and one or two sets of surface condensing plant. An advertisement contains further particulars, and specifications, &c., may be obtained from the manager (Mr. H. Dickinson), 1, Whitehall-road, Leeds. Tenders to town clerk (Mr. W. J. Jeeves) not later than 10 a.m. of 28th inst.

Worksop District Council require tenders for electricity generating plant, particulars of which are set out in an advertisement. Specifications, &c., may be obtained from the consulting engineer (Mr. A. B. Mountain), borough electrical engineer, Huddersfield, and tenders must be delivered to the clerk (Mr. Geo. H. Featherstone) not later than 23rd inst.

The Guardians of *West Ham* Union invite tenders for the erection of works detailed in an advertisement elsewhere. It will

Digitized by Google

be seen that the tenders are to include maintenance of the installation for 12 months from the date of completion of the whole of the works. The advertisement contains further important particulars of the conditions, and tenders have to be sent in to Mr. Fred. E. Hilleary, clerk to the Guardians, Union-road, Leytonstone, E., by Wednesday, May 16.

Bradford Corporation require tenders for the construction and delivery of two steam engines and two 1,000 kw. dynamos. Specifications may be obtained from the city electrical engineer (Mr. R A. Chattock), and tenders must be delivered to the town clerk (Mr. Frederick Stevens), Town Hall, Bradford, on or before 24th inst. An advertisement gives further particulars.

Bradford School Board invite tenders for the electric lighting of the Carlton-street school. Specifications from the consulting engineer (Mr. A. H. Gibbings), Old Bank-chambers, Cheapside, Bradford, and tenders to the clerk (Mr. Thos. Garbutt), School Board offices, Manor-row, Bradford, by noon of Monday next, 7th inst. See advertisement.

Heywood Corporation require tenders for electricity generating plant. Specifications, &c, from town clerk (Mr. J. H. Baldwick) and tenders by noon on May 14.

The Commissioners of the Royal Burgh of *Perth* invite tenders for 45 enclosed arc lamps and ornamental cast-iron and steel pillars, with switch gear, &c. Tenders before noon on May 7.

Salford Electric Light committee require tenders for two miles of low tension single cable, lead covered, and a battery of accumulators. Tenders by May 7.

Corporation of *London* Streets committee invite tenders for the supply on hire of electrically-driven dust carts. Tenders to town clerk (Sir John B. Monckton), Guildhall, E.C., by June 1.

Manchester Tramways committee invite tenders for 150 car trucks, tramway bonds and special track work and points and crossings. Tenders by May 7.

Paddington (London) Vestry invite tenders for carrying out certain proposed alterations to the existing electric lighting at the public baths. Tenders to vestry clerk (Mr. Frank Dethridge), Vestry Hall, Harrow-road, London, W., by May 14.

Burnley Corporation invite tenders for laying about 2,000yds. of cable. Tenders by May 14.

King's Lynn Corporation invite tenders for the supply of steam dynamos, boiler, switchboard and cables. Tenders by May 17.

Birkenhead Corporation invite tenders for steam pipe work, &c. Tenders by May 15.

Central Electric Supply Co. (*Ltd.*) invite tenders for the supply, delivery and erection of electricity generating plant. Tenders to Mr. F. J. Walker, 19, Carnaby-street, London, W., by 10 a.m. of May 22.

Rhyl District Council invite tenders for the supply and erection of electricity generating plant. Tenders to Clerk by 2 p.m. of May 14.

Brighton Corporation invite tenders for incandescent lamps for 12 months from July 1 next. Tenders by June 11.

The *Bengal Nagpur Railway Co.* (132, Gresham House, Old Broad-street, E.C.) require tenders for electric lighting plant. Tenders by May 10.

Maddelena (Italy) Municipal Council invite tenders and projects, until July 14, for public electric lighting.

TENDERS RECEIVED AND ACCEPTED.

The Southampton Harbour Board received 13 tenders for the supply and erection of a motor transformer. The estimate of the consulting engineer (Mr. J. G. W. Albridge) was £785.

British Schuckert Co. (*accepted*)	£690	Electric Construction Co.	£934
Edison and Swan Co.	1,145	Shalders and Davis	930
T. Scott Anderson and Co.	1,140	T. Richardson and Sons	870
General Electric Co.	1,029	Siemens Bros. and Co.	860
Thomas Barton	990	D. Bruce Peebles and Co.	830
Crompton and Co.	976	T. Parker (Ltd.)	694
Brush Co.	950		

Dundee Corporation have accepted the following tenders:—

Lowdon, Bros., traction switchboard	£1,000
British Insulated Wire Co., distributing mains	8,000
Callender Co., cables for electric lighting extensions	2,000

The Shoreditch (London) Vestry have referred tenders for the supply of cable from Messrs. Siemens Bros. and Co., the British Insulated Wire Co., and W. T. Glover and Co. to the Lighting committee for consideration. The Vestry have accepted the tenders of the Edison and Swan Co. and of the Berrenberg Electric Lamp Syndicate for the supply of incandescent electric lamps during the ensuing year.

The Maidstone District Council have accepted the tender of Messrs. Wallis and Sons for the erection of electricity station buildings at £8,563, and that of Messrs. Aiton and Co., 25, Laurence Pountney-lane, London, E.C., for steam pipes, &c., at £1,432.

Thirty-one tenders have been received for the electric lighting of the Northumberland County Lunatic Asylum, and the report of Mr. A. A. Campbell Swinton upon these tenders is to be considered at the meeting of the Visiting Committee on 21st May.

Leeds Corporation on Wednesday accepted the tender of the Electric Construction Co. for the supply of one, two, or three steam dynamos, for the Tramways department, at £10,149.

The Hart Accumulator Co. have secured the contract for the supply of storage batteries for the Penydaren electricity supply station, Merthyr Tydfil.

The Newcastle-upon-Tyne Tramways committee have let contracts for the ironwork for the tramcar sheds to Messrs. Swinney Bros, and to Messrs. Vipond and Co. for the ironwork for the power station at the Manors.

Rotherham Corporation have accepted the tender of Messrs. Thornton and Sons for erecting electricity station buildings at £8,351.

APPOINTMENTS VACANT AND FILLED.

The Greenock Board of Police require a resident electrical engineer at a salary of £300 per annum. Further particulars are given in an advertisement, and applications must be lodged with the town clerk (Mr. C. MacCulloch) before 10 a.m. of 9th inst.

Glasgow Corporation require an outside superintendent for their telephone exchange system. An advertisement contains additional particulars, and applications must be lodged with the town clerk (Sir J. D. Marwick) not later than May 11.

Leith Town Council require an engineer to take charge of their electricity undertaking. An advertisement contains further particulars, and applications to town clerk (Mr. T. B. Laing) not later than 12th inst.

An outside assistant is required by the Folkestone Electricity Supply Co. Applications to managing engineer (Mr. Thomas Hesketh). See advertisement.

The Newcastle-upon-Tyne Electric Supply Co. (55, New Bridge-street) require a meter inspector. Applications to secretary. See advertisement.

Rathmines (Dublin) District Council require a canvasser in connection with their electric lighting scheme. Applications to clerk (Mr. F. P. Fawcett), Town Hall, Rathmines, Co. Dublin, by 15th inst. See advertisement.

A foreman is required to take charge of the arc lighting department of an electricity undertaking. An advertisement gives further particulars.

Mr. H. Waring, of Burton-on-Trent, has been appointed electrical engineer by the Mexborough Council.

Liverpool Corporation have appointed Mr. P. M'Cullough works superintendent and general assistant of the tramways department, at £260 per annum.

Mr. R. Marshall, of Messrs. Siemens Bros. and Co., has been appointed mains superintendent at Ayr.

BUSINESS NOTICES.

New Firm.—We learn that Mr. F. J. Down is severing his connection with Messrs. Laing, Wharton and Down (Ltd.) and will shortly establish a business in London for supplying specialities for electric traction and lighting contracts. Mr. Down has been a much-respected member of the electrical industry from the early days and has 17 years' unique experience in every department. He enters business on his own account, we are sure, with the best wishes of all who have been associated with or have known him in the past, and with every chance of success in his new undertaking. Mr. Down was a founder of the firm of Laing, Wharton and Down in 1883, and has since that time had a large American and Continental experience and connection.

Messrs. F. R. Hill and A. V. Gifkins, hitherto trading as electrical and mechanical engineers under the style of Hill, Gifkins and Co., at 68, Victoria-street, London, S.W., have dissolved partnership. Business continues under the style of A. V. Gifkins and Co. by Mr. Gifkins, by whom all assets and liabilities will be received and paid.

Prof. Henry Adams, M.I.C.E, M.I.M.E., F.S.I., &c, of 60, Queen Victoria-street, London, E.C., has taken into partnership Mr. Hal Williams, A.M.I.M.E., A.M.I.E.E., &c., and the firm will in future be known as Adams and Williams. Mr. Williams was for some time with the Haslam Foundry and Engineering Co., Derby, and has until recently been principal assistant with Messrs. Bramwell and Harris of Westminster.

The necessity for more room for manufacturing purposes at the British Thomson-Houston Co.'s factory at 63, Bankside, London, S.E, has required the removal of the company's stores to more commodious quarters at Nos. 4 and 6, Bath-street, City-road, E.C.

The Universal Battery Co. have removed to Mid-Kent Works, New Beckenham, London, S.E. Telegrams: "Universal Beckenham." Telephone 133 Bromley.

BANKRUPTCIES, LIQUIDATIONS, &c.

The Motor Manufacturing Co. (Ltd.) is to be wound-up voluntarily for reconstruction purposes.

Digitized by Google

A meeting of G. R. Blot and Co. (Ltd.) will be held at 64, Cannon-street, London, E.C., on May 28, to receive an account of the winding up. Mr. A. Dodds Fairbairn is liquidator.

A meeting of the Wray Electrical Engineering Co. (Ltd.) will be held at Central Buildings, New-street, Huddersfield, on 29th inst., to receive an account of the winding up.

A first and final dividend of 9½d. will be payable on 18th inst. at the offices of Messrs. Yates and Scampton, 4 and 6, Wood-street, Bolton, in the bankruptcy (separate estate) of J. H. Clarke, general and electrical engineer (trading with B. Wild as Wild, Rothwell and Co.). A first and final dividend of 2s. 10d. will be payable at the same time and place in the separate estate of B. Wild.

Application for discharge was made last Friday at the London Bankruptcy Court by Walter Philip O'Reilly, manufacturing electrician, 397, Edgware-road. Bankrupt had failed three times. In 1880 he paid 2s., in 1888 6s., and in 1892 his liabilities amounted to £2,365, and assets realised £11. 2s., and consequently no dividend was paid. A further suspension of two years was ordered, the registrar remarking that the bankrupt had apparently been living upon his creditors.

Plant for Sale—The St. Andrew's Hospital (Northampton) authorities have some second-hand electric lighting plant for sale, particulars of which are set out in an advertisement. Applications to secretary.

Mr. Thomas Johnson, Prescot-street, Wigan, has some electric lighting plant for sale, particulars of which are set out in an advertisement in another column.

For Disposal.—There is advertised elsewhere for disposal a private telephone wire with rights of way extending from the west to the north-west of London.

Jandus Arc Lamp—Messrs. Drake and Gorham inform us that during last year, in addition to the ordinary sales, several large installations of Jandus lamps were erected, including the Bon Marché, Brixton (250 lamps); John Barnes and Co., Hampstead; Matthew Rose and Son, Hackney; Gardiner and Co.'s branches at Woolwich and Clapham Junction; and the lighting of Burlington-arcade, Piccadilly, London. Large installations now in hand include the lighting of the Mazawattee Tea Co.'s factory with 180 lamps, and a similar number for a large shipbuilding firm. Considerable success has been obtained with Jandus lamps on high voltage circuits, and they are used four and five in series for street lighting at Chester, Shrewsbury, Darwen, and will also be installed at Fleetwood and Epsom. The Jandus Co. have recently introduced a new pattern lamp for power circuit and street lighting service, with automatic cut-out and resistances self-contained. Some 40 of these lamps are in satisfactory operation on the City and South London Railway, burning direct off the power circuit. Several improvements have been made in the standard pattern lamps, notably in the direction of long burning hours, and the Jandus lamp is claimed to be now far ahead of its competitors in this respect. Messrs. Drake and Gorham are now putting on the market the new Jandus spherical globe lamp, which has been designed to meet the demand for an efficient and serviceable lamp at a lower price than the standard Jandus pattern. They also hope shortly to announce the issue of the Jandus alternating lamp, the preliminary trials of which have proved satisfactory.

Hart Accumulators.—A tastefully-designed hanging show card of the Hart Accumulator, showing a grid section and the company's patent non-corrosive terminal, is sent out by the Hart Accumulator Co., and copies can be obtained by the trade on application to the works, Marshgate-lane, Stratford, E.

"Stellite" Fittings.—A comprehensive and well-illustrated list of "Stellite" electric fittings is now ready for the trade, and can be obtained of the British Electric Works Co. (Ltd.), Cheston-road, Aston, Birmingham. The list includes particulars and prices of the cable connector and terminal recently described in these columns.

"General" Electric Plant.—Circular No. 26 of the General Electric Co. (Ltd.) illustrates accessories for X-ray work, a new pattern focussing hand feed arc lamp, &c. The General Electric Co. are supplying free to the trade a useful foot-rule for the desk or draughtsman's table, containing a quantity of information often required at sight.

B.T.H Plant.—Q.B. (quick break) switches are described and illustrated in pamphlet No. 62 issued by the British Thomson-Houston Co.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from April 25 to May 1, with the ports of destination:—

Africa—Alexandria, £183 (including £45 telegraph material); Cape Town, £5,875 (including £4,100 telegraph material); Chinde, £54; Durban, £6,432 (including £5,946 telegraph plant); East London, £29. *Argentina*—Buenos Ayres, £30. *Australasia*—Adelaide, £61; Brisbane, £123; Melbourne, £1,131 (telegraph material); Sydney, £957; Wellington, £20. *Brazil*—Rio Janeiro, £198 (telegraph apparatus). *Ceylon*—Colombo, £747 (including £724 telegraph cable). *Chili*—Boca, £425 (telegraph material). *China*—Shanghai, £323 (and 24 tons old telegraph wire); Tientsin, £118 (telegraph material). *Germany*—Hamburg, £135. *Holland*—Amsterdam, £280. *Hong Kong*, £51. *India*—Bombay, £55; Calcutta, £689; Madras, £39. *Japan*—Kobe, £91; Yokohama, £318. *Straits Settlements*—Penang, £103 (telegraph material); Singapore, £268 (including £107 telegraph material). *Sweden*—Gothenberg, £25. Total £18,765, against £10,076 for the corresponding week last year (April 26 to May 2).

COMPANIES' MEETINGS AND REPORTS.

Indo-European Telegraph Co. (Ltd.).

The thirty-third ordinary general meeting of the members of this company was held at Winchester House, Old Broad-street, on Monday, under the presidency of J. HERBERT TRITTON, Esq.

The SECRETARY (Mr. L. Pagenkopf) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN, in moving the adoption of the report and accounts, and the declaration of the dividends therein set out, said: Gentlemen, since our last annual meeting, Sir William Brooke, formerly Director-General of Indian Telegraphs, has joined our Board, and his great experience in telegraph matters, particularly of Indian telegraphs, has already proved most helpful to us in our deliberations. The year as to which we are now presenting our report has brought before us an exceptional number of important questions. When last we met, some apprehension was expressed as to wireless telegraphy—apprehension reflected at that time in the falling prices of most telegraph companies' shares; but its commercial value has yet to be proved, and to-day it is not of much, if any, importance. A more important subject—namely, a reduction in telegraphic rates between this country and the East, has been widely agitated during the year, and great pressure is still being exercised in order to bring it about. Your Directors have no wish whatever to stand in the way of a reasonable reduction in the rate of 4s. per word at present in force, but we must bear in mind that in our case the approval and assent of the Governments interested is necessary for any measure of this sort. I am bound to say that it appears highly problematical to me that reduced rates between this country and India will be followed by any large increase of traffic. The conditions of Indian trade and enterprise are wholly different to those of young and growing European communities, stimulated to quite an extraordinary degree by discoveries of gold. Apart from a few great firms, the natives of India have no sort of relation with Europe, and will send no telegrams whether rates be low or high. Quite 90 per cent of our traffic is in code, and the cost per word—per plain word—must be a very few pence. In fact, taking minimum distances into consideration and the risks involved, whether to land lines or cables, the tariff at present seems to us by no means excessive. But we recognise certain anomalies, and, as I have said, we will not stand in the way, provided the Governments, and especially our own concessionary Governments, do not object. The report has already informed you of the gratifying intelligence that, after negociations extending over a very considerable period, our Russian and Persian concessions have both been renewed for a further period of 20 years from 1905—thanks to the benevolent consideration given to the question by these Governments, and—may I add—to the persevering efforts of the company. The working of the line through Russia will remain in our hands, as at present, but, in accordance with the terms of the original concession, the ownership of the line will from the date named vest in the Russian Government. Our tolls have been increased, and a minimum annual payment insisted upon. Though the bargain is a somewhat hard one, we are gratified at its conclusion. As regards the German concession,—the only remaining one—the preliminaries for an extension to the same term have been settled with the Imperial German Telegraph Department, and the Directors have every confidence in anticipating the same benevolent consideration by the German Government itself. That you will consider, I am sure, a very satisfactory announcement. It means years of patient negotiation successfully accomplished. The working of the year has resulted in a somewhat better balance of profit than the preceding year, the receipts having been increased by £7,700 and the expenditure remaining practically the same. A duplicate cable has been laid in the Straits of Kertch, and we have in prospect the necessity of considerably strengthening other sections also, with a view of still further avoiding interruptions to the working from climatic and other difficulties. We have therefore thought it desirable to place to reserve a larger sum than before. The proprietors will have read in the report the announcement of the retirement of Mr. W. S. Andrews from the post of managing director, so successfully filled by him for so long a period. We are glad to say that he will continue to sit on the Board as an ordinary director, and we shall thus have the benefit of his great experience and knowledge. The Board propose, subject to your approval, to grant him a retiring pension of £1,200 per annum, which is practically on the Government scale, and we doubt not you will do this with unanimity. Mr. T. W. Stratford-Andrews, who has been thoroughly trained in electrical and engineering works and administrative business, and who is acquainted with every section of our line, as well as the commercial work of the company, will take his place as managing director. Two members of the staff also have been accorded pensions—Mr. Moll, late secretary, and Mr. Nelson, lately our representative in

Digitized by Google

Teheran, both of whom also have served us from the commencement. In all cases, though the vacancies have been refilled, the totals paid in salaries show reduction; and the pensions are, of course, conditional on the continuance of the concessions. It may be that we shall submit to you a general scheme for pensions at our next annual meeting. We have one in contemplation. Another matter which I may perhaps mention to you is the following letter from the General Post Office, dated April 12, which was received by the managing director a few days ago, and which speaks for itself: "I am directed by the Postmaster-General to acknowledge the receipt of your letter of yesterday's date respecting the reduction in the rate for soldiers' and sailors' telegrams between Australia and South Africa, and to request that you will be so good as to convey to your Directors his warmest thanks for their approval of the arrangement suggested in the letter from this Department on the 9th inst." That is, that soldiers' and sailors' telegrams between Australia and South Africa are conveyed at half rates—2s. per word instead of 4s. A telegram has just been placed in my hands relating to an arrangement which we have made—as before—to supply the Shah of Persia with telegraphic messages at any time during his tour in Europe, which has now commenced, and which I am sure his Imperial Majesty will appreciate. In conclusion, we are glad to be able to inform you that the cordial relations which have always existed between this company and its concessionary Governments continue and we have every reason to hope will continue. I have now much pleasure in moving the resolution.

Mr. C. HOLLAND seconded the motion, which was carried unanimously.

The following resolution was then carried unanimously—

"*Resolved that a pension or allowance of £1,200 per annum from the 1st of Jan. last be paid to Mr. W. S. Andrews during his life, or until the further prosecution of the undertaking of the company shall be rendered impracticable by the action of any of the Governments by which the concessions under which the undertaking is now worked have been granted; the arrangement, however, to be subject to revision in case the dividend payable by the company shall fall below 5 per cent.*"

Mr. W. S. ANDREWS: Mr. Chairman and gentlemen, I am very much indebted to you for this resolution. The Chairman has expressed himself eloquently—perhaps rather too favourably—respecting the services I have been able to render to the company; but I may say of those services that they have been so largely facilitated, and so much backed up, by the aid of the Directors, that they are as much responsible as I am for the present well-being and prosperity of the company. It is a prosperous concern, and I am pleased to say that we have all of us—and I am a shareholder myself—done very well indeed. I beg to thank you most warmly for your kindness.

The re-election of Mr. W. S. Andrews and Mr. John von Berenberg Gossler, the retiring Directors, was then approved, and the auditors, Messrs. Kemp, Sons and Co., were re-appointed. A cordial vote of thanks to the chairman, directors, and officials of the company terminated the proceedings.

Cuba Submarine Telegraph Co. (Ltd.).

The report of the directors of this company for the half-year to Dec. 31 announces that the total receipts amount to £19,512. 18s. 6d., and the gross expenditure to £6,192. 2s. 3d., leaving £13,320. 16s. 3d., which, added to £4,582. 7s. 6d. brought forward, leaves £17,903. 3s. 9d. at credit of revenue account. The traffic receipts show a considerable falling off compared with the corresponding period of last year, due principally to the reductions in rates and the competition of the Government land lines in the island of Cuba. £4,937. 16s. 6d. has been added to reserve, which, after deducting £2,937. 16s. 6d. for cable repairs, now stands at £130,000.

The preference dividend will absorb £3,000, and leave £9,965. 7s. 3d., out of which the directors recommend the payment of a dividend at the rate of 6 per cent. per annum on the ordinary shares (free of tax), the balance (£5,165. 7s. 3d.) being carried forward.

Since the last report the Cape Cruz-Manzanillo cable has been repaired, and the cables have remained in good working order, with the exception of the broken Cienfuegos-Cape Cruz cable, which has been abandoned, as the efforts to repair it had to be given up in consequence of its decayed condition. The section is still duplicated by the coast cables, and for the present it is not proposed to replace this cable.

The Foreign Office is continuing its negotiations with the United States of America concerning this company's concessions, payment of subsidy and claims for damage done to the cables during the Spanish-American war. Mr. Keith and Mr. Scott have lately visited America in connection with these negotiations, the settlement of which is still pending.

Great Northern Telegraph Co. (Ltd.).

The annual meeting of this company was held at Copenhagen on April 28.

The chairman and managing director, Comm. E. SUENSON, D.R.N., in rendering an account of the working of the company, said that during the first half of 1899 the condition of their cables was most satisfactory, whilst, in the latter half, numerous interruptions occurred, especially in Europe. Twenty interruptions had affected eleven of the European cables, and in the Far East there had been nine interruptions of six cables. The number of interruptions compared favourably with that of the preceding year. The cable steamer "H. C. Örsted" had been employed on active service for 134 days, and the "Store Nordiske" for 87 days, of which 25 were for the account of others. The efforts of the Imperial Russian Administration to improve the Wladiwostock line had commenced to bear fruit, and although there was still room for improvement, the number of telegrams forwarded showed an appreciable increase. On the expiry of their Danish concessions for the establishment and working of cables connecting Denmark with Norway, Great Britain and Russia, the Danish Government extended the same with certain modifications, the former to Jan. 1, 1911, and the latter to Dec. 31, 1912. At the meeting of the International Meteorological Committee at St. Petersburg in September last, the project for a submarine cable to connect Iceland with the telegraphic system of the world was again favourably received, the Committee, by a special resolution, urging the Danish Government to continue their efforts for the realisation of the project. The Danish Government were less successful in their endeavours to induce the Peace Congress, assembled at the Hague in May and June last, to deal with the question of the legal status of submarine cables in time of war. In the Far East the company had obtained an extension till 1911 of the privileges previously granted them by the Chinese Government, and the China traffic had attained the same level as during the preceding year, whilst the Japan traffic showed an increase. If this satisfactory state of affairs was maintained during the present year, there would possibly be occasion to take up the question of a further revision of rates for telegrams to the Far East, at the International Telegraph Conference to be held in London next year. The excellent results of the year enabled them to pay the same extra dividend as last year—viz., 7½ per cent. (making 12½ per cent. for the year), and at the same time to increase the reserve and renewal fund by a substantial amount. The political events of the past year had more than ever emphasised the important part played by the great telegraphic highways in the political, commercial, and social development of the world. In addition to the old English and American schemes, whose principal object was the establishment of national and independent submarine lines in the Pacific, other schemes and projects with similar aims had sprung up in other parts of the globe. As yet it was difficult to disentangle the numerous ideas and projects, and to foretell the issue, but they confidently hoped that, thanks to the political passivity and neutrality of the nation to which they belonged, and to the admitted discretion and impartiality of its service, the company would continue to enjoy the confidence of all the Governments and administrations whose territories its cables had connected for 30 years. Nevertheless, it was more than ever necessary to prepare for any contingency which might arise from the present complications, by continuing the cautious financial policy which they had followed till now.

The report and accounts were then adopted.

Western Telegraph Co. (Ltd.).

The report of the directors of this company for the half-year to Dec. 31 states that the revenue amounted to £139,596. 7s. 10d., and the working expenses to £25,596. 0s. 11d. After providing £3,200 for debenture interest and sinking fund, and £1,516. 6s. 4d. for income tax, there remains £109,284. 0s. 7d.; to this is added £5,062. 16s. 3d. brought forward, making £114,346. 16s. 10d. Further expenses consequent upon carrying out the arrangements for closer working union with the Western and Brazilian and the London Platino-Brazilian Telegraph companies amounted to £176. 17s. 4d. First and second interim dividends amounting to £62,379 have been paid, and £45,000 transferred to reserve, leaving £6,790. 19s. 6d. to be carried to next account.

In accordance with the terms of the trust deed the first quinquennial examination of the staff pension and superannuation funds has recently been made, with the result that the funds are reported by the actuary to be in a satisfactory condition; they do not, however, admit of the retiring age being reduced from 60 to 55 years, which experience proves would be most desirable. The actuary advises that in order to bring about this change the contributions by the staff and the company to the pension fund would have to be increased from 2½ per cent. to 4 per cent. respectively. It is believed that the staff will readily agree to assume this additional liability, and a resolution will be submitted to the forthcoming meeting of shareholders authorising the directors to increase the company's contribution from Jan. 1, 1900, to 4 per cent., and to provide a sum sufficient to enable the trustees to pay the pensions which have already been purchased to Dec. 31, 1899, at the age of 55 instead of 60 years, the company guaranteeing to make up the loss (if any) that there might be in the fund on account of such reduction.

Submarine Cables Trust.

The report of the trustees states that the revenue for the year to April 15, 1900, including £81. 11s. 9d. from previous accounts, amounted to £24,870. 7s. The expenses amounted to £1,269. 7s. 1d., and the payment of coupons to £20,286, together £21,555. 7s. 1d., leaving £3,314. 19s. 11d. In accordance with the terms of the trust deed, 27 certificates have been drawn by lot for redemption at £120 per certificate, absorbing £3,240, and leaving £74. 19s. 11d. to be carried forward. The Commercial Cable Co. having offered to its shareholders a proportion of new shares, amounting to one-third of their existing holdings, at par, the trustees unanimously agreed to accept the offer on behalf of the Trust, and at the same time to sell £1,200 Anglo-American Telegraph Co.'s preferred stock to meet the cost. A small balance remaining has been invested in the purchase of £15 Eastern Telegraph Co.'s ordinary stock. At an extraordinary general meeting of the certificate holders on July 28 last, Mr. Clement Sneyd Colvin, C.S.I., was appointed a trustee.

Calcutta Electric Supply Corporation (Ltd.).

The directors' report for the year to Dec. 31 states that the supply of electrical energy commenced on April 17, 1899, and at Dec. 31 there were connected to the company's mains the equivalent of 9,463 8 c.p. lamps, of which 8,170 were for lighting and 1,293 for power. 54,897 units were sold (42,947 for lighting and 14,859 for power), and the gross revenue was

Digitized by Google

£2,041. 12s. 2d., while the costs, after charging management and administration expenses to revenue, amounted to £1,389. 16s. 5d., leaving a net profit of £651. 15s. 9d., which it is proposed to carry forward. Applications in considerable numbers continue to come in from new customers, and the few wiring contractors in Calcutta are kept well employed. Landlords, both European and native, show a willingness to pay for the electric wiring required by their tenants. It is reported that the design of the whole station and mains is good, and that the supply of electricity has given general satisfaction.

At the time of the formation of the company it was not estimated that any important revenue would be derived from the supply of current for motors, but the use of fans driven by electric power in place of punkahs has become quite popular. It is reported that 2,000 are supplied or on order for use during the hot weather, and the fact that a large proportion will be running during the 24 hours for at least eight months of the year indicates that the employment of electric fans will probably form a large and lucrative source of revenue to the company.

The Government of India is desirous of passing a general Electric Lighting Act for the whole of India, to supersede the present Calcutta Electric Lighting Act, and Messrs. Crompton and Co. have, with the assistance of the directors of this company, prepared a draft of the proposed new Act, which is now under consideration. The difficulties in connection with the extension of the company's licence to the period of 42 years have been removed, and the Government of Bengal have agreed to the renewal, and also to the addition to the original area of large districts to the south of Calcutta, including the Alipore and Ballygunge suburbs. Additional mains have been laid in many of the streets in Calcutta beyond those comprised in the original contract; many more will soon be required, and further considerable capital expenditure will have to be incurred for the supply to the new districts. The directors therefore propose that the nominal capital of the company be increased to £200,000 by the creation of 20,000 additional shares of £5 each.

There are many other towns in India where electricity may, no doubt, be profitably employed, and the directors are in negotiation for the necessary powers to supply some of these places. Should these negotiations prove successful, the shareholders will be called together to consider, and, if approved, to sanction these schemes and to provide the capital required.

CORK ELECTRIC TRAMWAYS AND LIGHTING CO. (LTD.)—The report of the directors of this company, for the year 1899, states that the result of the year's working shows: Receipts, £26,909. 19s. 7d.; working expenses, £15,367. 14s. 10d.; profit, £11,542. 4s. 9d.; balance forward, £55. 12. 8d.; total, £11,597. 17s. 5d. Interest on debentures has required £2,152; interest on loans, £1,112. 10s. 11d.; bad debts (lighting), £37. 6s. 9d.; proportion of preliminary expenses written off, £213. 6s. 9d.; total, £3,515. 4s. 5d.; leaving £8,082. 13s., and the directors recommend the following dividends: 5 per cent. on cumulative preference shares (£2,823), and 5 per cent. on ordinary shares (£3,303. 16s. 9d.). A large portion of the capital expenditure appertaining to the lighting and a certain portion to the tramways were not of earning capacity during 1899, and the directors therefore regard the results of the first year's operations as satisfactory. £1,758. 8s. 7d. has been carried to reserve and depreciation. The balance of 7,000 ordinary and 7,000 cumulative preference shares, and 548 4 per cent. debentures of £100 each have been issued. The nominal capital of the company has recently been increased to £200,000, in 10,000 ordinary and 10,000 5 per cent. cumulative preference shares of £10 each. An extension of the tramways to Ballintemple was opened in July last for public traffic. It has been found necessary to purchase ten additional motor cars and to extend the car depot. The lighting plant has been considerably increased, and the necessary extensions to the power house carried out. The provisional order for lighting has been acquired from the Queenstown Commissioners, and the work is in course of execution. The supply of current for private lighting has recently been commenced at Queenstown. A contract has been concluded with the Cork Corporation for public lighting, and arrangements are completed for public lighting in Queenstown on similar terms to those of Cork. The company is promoting a bill in Parliament for the extension of the tramways from Ballintemple to Blackrock, and an order in Council has been issued authorising an extension of the line along the Western-road. At the meeting of the company on Tuesday the directors' report was adopted.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL CO. (LTD.)—The directors' report for the year ended Dec. 31 last, states that the debenture stock has been increased from £60,000 to £75,000, and the increase of the loan to the Metall Co. to £73,190, and that the preference shares issued have been increased to £50,000. The dividend of 3s. per share paid to the preference shareholders on May 1, 1899, absorbed £3,348, and debenture interest £5,501. The patent charges are heavier than usual, owing to the cost of working the company's patents in Austria and Hungary, and to charges in connection with the patents for an improvement in steam pipe-joints (invented by Mr. Preschlin, manager of the Schladern Works), which has been taken up by the company. The sales and gross profits of the Metall Co. show a considerable increase compared with the previous year, the profit on trading account being £18,209, against £13,749. The directors report that the past year was one of considerable difficulty owing to the phenomenal rise in the price of copper, and to the scarcity and consequent high price of coal. Owing to the prosperous state of trade in Germany, difficulty was experienced in obtaining labour. The increase in the price of copper not only restricted the placing of orders, but in the case of contracts, which the company had with a large shipyard and the railways, caused actual loss. The rise was also responsible for an increase of £10,000 additional working capital, which the directors had to raise, entailing an increase in debenture interest. The largely-increased demand for the company's manufactures has necessitated considerable extensions to both plant and buildings. After setting aside the usual reserve, the directors of the Metall Co. have declared a dividend equal to 120,000 marks, or £5,853, from which has to be deducted the charges of the Austrian Co. for the past year (£4,133). From the balance the directors recommend the payment of a dividend of 3¾ per cent., or 1s. 6d. per share, less tax, to the preference shareholders. The one-tenth of the net profit due to the ordinary shareholders not being sufficiently large is added to the amount already standing to their credit.

NEW COMPANIES, STATUTORY RETURNS, &c.

ADELAIDE ELECTRIC TRAMWAYS (LTD.)—This company was registered on April 12, with a capital of £3,000, in £1 shares, to carry on the business of electrical and general engineers, tramway and railway proprietors, accumulator and dynamo manufacturers, electricians, &c. The subscribers are J. A. Kelman, D. Sluter, H. Yuill, D. E. Kelman, C. S. Kelman, S. Gibbs, and G. C. Eedes.

BANBURY AND DISTRICT ELECTRIC SUPPLY CO. (LTD.)—This company was registered on April 24, with a capital of £25,000, in £10 shares, to carry on the business of electrical engineers, electricians, tramway and light railway proprietors, suppliers of electricity for light, heat, and power, manufacturers of electrical apparatus, &c. The subscribers are W. L. Magden (electrical engineer), E. Hopwood, C. Walmsley, J. Renwick, M. E. Sheerboom, J. S. Raworth (civil engineer), and G. J. Tindall.

COMPRESSING MACHINERY CO. (LTD.)—This company was registered on April 23, with a capital of £10,000 in £1 shares, to carry on the business of mechanical, electrical, and general engineers, leather waste merchants, &c.

COUNTY OF KENT ELECTRICAL POWER DISTRIBUTION CO. (LTD.)—This company was registered on April 24, with a capital of £25,000, in £10 shares. The objects, subscribers, office, and particulars are the same as in the Banbury and District Electric Supply Co.

COUNTY OF NORTHAMPTON ELECTRIC POWER AND TRACTION CO. (LTD.)—This company was registered on April 24, with a capital of £25,000, in £10 shares. The objects, subscribers, office, and particulars are the same as in the Banbury and District Electric Supply Co.

COWPER INVENTIONS DEVELOPMENT CO. (LTD.)—This company was registered on April 24, with a capital of £50,000, in £1 shares, to adopt an agreement with Mr. S. Cowper-Cowles, and to carry on the business of electrical and general engineers, engineers, machinists, tool makers, &c.

MARCONI INTERNATIONAL MARINE COMMUNICATION CO. (LTD.)—This company was registered on April 25, with a capital of £350,000, in £1 shares, to acquire certain licenses and powers from Marconi's Wireless Telegraph Co. (Ltd.), to carry on the business of electrical and general engineers, and to manufacture and deal in wires, cables, telegraphic apparatus, &c. The subscribers are Major S. Flood Page, H. S. Saunders, H. H. Allen, P. H. Stewart, F. S. Tomkins, J. McGowan, and W. H. Benham. The first directors are M. Balser, Col. Thys, M. Travailleur, M. de Volder, J. F. G. Bannatyne, G. Marconi, A. Ochs, Major S. Flood Page, H. S. Saunders, and Sir C. Euan-Smith. Marconi's Wireless Telegraph Co. (Ltd.) may appoint three directors.

NATIONAL CONSTRUCTION CO. (LTD.)—This company was registered on April 28, with a capital of £10,000, in £1 shares, to carry on in London the business of electrical engineers, manufacturers of conduits, cables, wires, lines, accumulators, &c., for electrical and other purposes, suppliers of electricity for light, heat, or power, &c. The first directors are H. R. Gamble, E. S. Perrot, G. J. Jackson, and F. W. Abbot.

RAILWAY AND GENERAL ENGINEERING CO. (LTD.)—This company was registered on April 25, with a capital of £80,000 in £1 shares, to carry on the business of dynamo makers, engineers, tool makers, &c.

ROBERT ROGER AND CO. (LTD.)—This company was registered on April 24, with a capital of £30,000, in £1 shares, to acquire the business now carried on under the style of Robert Roger and Co., and to carry on the business of electricians, engineers, founders, &c.

ROYLES (LTD.)—This company was registered on April 25, with a capital of £150,000 in £1 shares, to acquire the business carried on by Mr. J. J. Royle, and to carry on the business of iron and brass founders, mechanical and electrical engineers, tool makers, &c.

SOUTH SHIELDS ENGINEERING CO. (LTD.)—This company was registered on April 28, with a capital of £2,000, in £1 shares, to carry on the business of electricians, electrical engineers, suppliers of electricity, manufacturers of electrical apparatus, &c. The subscribers are T. W. Ogilvy (electrical engineer), C. R. Toomer (engineer), J. T. Atkin, A. Purvis, A. P. Stainton, C. Macdonald, and F. McKenna (engineer).

THAMES VALLEY ELECTRIC SUPPLY CO. (LTD.)—This company was registered on April 24, with a capital of £25,000, in £10 shares. The objects, subscribers, office, and particulars are the same as in the Banbury and District Electric Supply Co.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Jan. 25, 1900). Price of silver 27 5/16d. per oz. (May 3). Consols (2¾ per cent.) 100⅜—100½ for money, 100⅞—100¾ for account; 2½ per cent. 97⅛—98⅛ (May 3). Stock Exchange Settling Day: Consols, May 4; Stocks and Shares Continuation Days, May 14 and 29; Ticket Days, May 15 and 30; Pay Days, May 16 and 31; Mining Share Carry-over Days, May 11 and 28.

AFRICAN DIRECT TELEGRAPH CO. (LTD.)—A list of the numbers of 140 £100 sterling 4 per cent. mortgage debenture bonds of this company,

Digitized by Google

which have been drawn for payment on July 2 at Parr's Bank, Bartholomew-lane, is given in an advertisement in another column.

GREAT NORTHERN TELEGRAPH CO. (LTD.)—Coupons for 1899 (No. 48) of this company's shares should be presented for payment at Messrs. C. J. Hambro and Sons, 70, Old Broad-street, London, E.C.

HAMPSTEAD ELECTRIC SUPPLY CO. (LTD.)—The report of the directors for the first year has been issued. No dividend is declared on either the ordinary or preference shares.

LONDON PLATINO-BRAZILIAN TELEGRAPH CO. (LTD.)—Notice is given that the twenty-second ordinary general meeting of this company will be held at Winchester House, London, E.C., on Tuesday, May 8, at noon. The register of members and transfer books is closed from May 1 to 8 inclusive.

POTTERIES ELECTRIC TRACTION CO. (LTD.)—Subscriptions are invited to an issue of £125,000 4½ per cent. debenture stock of this company at 105 per cent.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee has ordered the $3,333,300 additional capital stock of the *Commercial Cable Co.* to be quoted in the official list. Application has been made to the committee to appoint a special settling day in and to grant a quotation to the further issue of 30,000 £5 ordinary shares and 30,000 £5 6 per cent. cumulative preference shares of the *British Insulated Wire Co. (Ltd.)*, and to allow the £10 shares of the *Cape Electric Tramways (Ltd.)* to be quoted in the official list.

SUBMARINE CABLES TRUST.—The list will be found in another column of 27 certificates of this Trust which were drawn for payment by Messrs. Glyn, Mills and Co., 67, Lombard-street, London, E.C., on and after April 27.

UNION ELEKTRICITATS GESELLSCHAFT (BERLIN).—This company, which has a share capital of 24,000,000 marks (£1,200,000), proposes to issue debentures to the extent of 10,000,000 marks for the expansion of the business.

WEST COAST OF AMERICA TELEGRAPH CO. (LTD.)—The report of the directors for the year ended Dec. 31 announces that the gross income for the year 1899 was £28,347. 9s. 8d., against £25,080. 1s. 4d. in 1898, and the working expenses £21,065. 0s. 4d., compared with £18,840. 15s. 1d. After providing interest on the 4 per cent. debentures (£6,000) and on the 4 per cent. income bonds (£800), the net balance of profit was £482. 9s. 4d., and with £273. 16s. 1d. brought forward there remains £756. 5s. 5d., out of which the directors have appropriated £500 in reduction of the expenses of reconstruction, leaving £256. 5s. 5d. to be carried forward. During the year there was a general improvement in trade on the West Coast, and the rate of the Valparaiso exchange on London rose to 16d. The company's cables, land lines, and the repairing steamer have been kept in a state of efficiency.

ELECTRIC TRAMWAY AND RAILWAY TRAFFIC RECEIPTS.

NOTES.

The wag who said that single misfortunes never come alone, being a member of Parliament, might also have observed that the same peculiarity attaches to electrical bills. It never rains them but it pours them. Rarely have the Committee rooms of the Houses of Parliament been so much the resort of electrical engineering experts as they have been during the past week and are likely to be for some time to come. Besides the five power bills before the Select Committee presided over by Sir James Kitson, and the bill of the same nature for the North Metropolitan Electric Power Supply, to be heard by another Committee, there are a large number of electric railway and tramway bills. Probably the most interesting of these, from the point of view of the general electrical public, is that relating to the proposed express railway between Manchester and Liverpool. The railway presents many novel features: it is to be constructed on the Lartigue mono-rail system, its cars are to run at 110 miles an hour, it is largely to be an overhead line, and is to hav only the two stations. Vigorous opposition to this bill is being raised by several large railway companies, by the Mersey Docks and Harbour Board, and of course by local authorities. Altogether there are no less than thirty electrical bills which have either just passed, or are now passing through, the Committee stage of their more or less precarious existence.

Work for electrical experts has also been provided by the two legal cases reported in this issue, which afford excellent lessons in patent law, and both of which involve directly and indirectly interests affecting a considerable section of the electrical industry. The one case, that of "Chamberlain and Hookham *v.* the Bradford Corporation," raises the important question whether the Thomson meter when employed on so-called constant-pressure mains is an infringement of the Hookham meter patent, but as this case is still undecided we can offer no comment on it at this stage. We will call our readers' attention, however, to the abstracts of patents, &c., given as an appendix to our report of the case in another column with a view to enable the evidence to be easily read and properly appreciated.

The Jandus—Johnson & Phillips case is interesting, but in a way disappointing. We do not refer to the judgment, which could hardly have been otherwise on the evidence, but to the tantalising fact that, although aspersions were cast on the validity of the master patents covering the enclosed arc lamp, no decision could be given on this point. The defendant in the case, being a licencee under the patents, could not contest their validity, and was liable to pay royalties to their owners whether the patents are valid or not if it could be proved—as was done—that he manufactured a lamp corresponding to the description in the patents. If on a future occasion the validity of the patents owned by the Jandus Co. is to be contested, a large portion of the same evidence will have to be gone through again.

On Wednesday evening, Fellows of the Royal Society once again enjoyed what is popularly termed their "black" conversazione, the black-coat sex being alone admitted. As usual, the proceedings were of a sombre character, while the number and interest of the exhibits was undoubtedly lower than usual. Electrical exhibits, moreover, were among the least rather than the most attractive, the greater number being decidedly commonplace in character. There were, of course, praiseworthy exceptions, notably Mr. A. P. Trotter's timely exhibit of models illustrating leakage from electric tramways. These consisted in surfaces constructed on three Cartesian axes, the vertical representing potentials distributed over the space adjacent to the tramway. Equipotential lines, found experimentally by Prof. W. G. Adams's method, were shown in black, and lines of current flow were drawn therefrom in red.

A rather obvious converse to De la Rive's experiment with a floating battery was shown by Prof. Silvanus Thompson—little floating magnets enclosed in glass tubes taking the

Digitized by Google

place of the battery. An immersed hollow coil carrying an electric current provided a sub-aqueous magnetic field by which the vagaries of the magnets were determined. Mr. RICHARD KERR showed a clock controlled by Hertzian waves, the maximum distance at present over which this feat has been performed being about six miles. Lightning conductors from St. Paul's Cathedral were shown by Mr. K. HEDGES, and a compact but powerful influence machine constructed of twelve vulcanised plates, by Mr. WIMSHURST. Mr. P. E. SHAW exhibited the ingenious electric micrometer recently described before the Physical Society and referred to in *The Electrician*, Vol. XLIV., p. 805.

MR. GAINE'S statistics at the National Telephone Co.'s staff dinner last Friday showed that the competition in store for the company has not decreased the magnitude of its business. The company now owns 968 exchanges, representing upwards of 176,000 subscribers' telephones, which is one for every 214 of the population of the United Kingdom. During the year the net increase of subscribers has been 21,000, and 617 million messages have been sent (reckoned on the basis of one conversation = two messages). In view of the steps which are being taken by the Post Office and by certain municipalities, it would have been interesting to have heard how the advance in London itself, and, say, Glasgow, Manchester, and Huddersfield, compared with that of previous years, exclusive of other districts in which no more serious competition than hitherto has been announced. Mr. GAINE gave no indication of what the future policy of the company is to be with regard to the competition with its licensor, but he could not restrain himself from directing one poignant shaft towards this august Department. Every day delays of from half-an-hour to two hours in obtaining trunk connections were complained of owing to the insufficiency of trunk lines. If, said Mr. GAINE, the two millions which the Post Office has had voted for needless competition in London had been applied to improving the trunk service, it would have been spent to better advantage.

MUCH was said as to the complaints made by ignorant critics, and they were likened—hardly with justice—to the criticisms levelled at our generals in South Africa and at the War Office. Lord KELVIN attributed everything unsatisfactory to the unbusinesslike arrangements of the users, and placed a large proportion of the blame on the *genus* office boy. Yet there is no doubt that, whether we are better or worse off in that respect than other countries, many of the complaints made are justified; and, from what we know of the excellent efficiency of the system from an engineering point of view, we do not doubt that cases of negligence of the operating staff cannot be so infrequent as is desirable. This is no doubt inseparable from a huge business employing a staff of some 10,000 or 11,000, but we cannot but think that it would be minimised if more attention were given to the organisation of the complaints department. Cannot the subscribers themselves be taught to make their complaints in such a specific way that the cause of the deficiency can be arrived at in each case? With an organisation as complete as that of the National Telephone Co., a complaint made by a *calling* subscriber, giving the time and the details of his ineffective demand, should enable the company to trace the negligent operator. On the other hand, complaints by the *called* subscriber are, in consequence of the switching arrangements of every large telephone system, much more difficult, if not impossible, to trace, and they should be discouraged, the subscriber being asked to devote the maximum of businesslike method to the complaints of failures to obtain connections. By thus lessening the number of complaints to be sifted, and increasing the accuracy of each one, an amelioration in the service should result.

The Royal Society.—Among the Papers down for reading yesterday was "The Radio-Activity of Uranium," by Sir W. Crookes, F.R.S.

Electrical Standardizing, Testing and Training Institution.—Prof. C. A. Carus-Wilson will commence a special course of lectures upon "The Construction and Use of Motors" to the students of this institution on Monday, 28th inst.

Municipal Trading as a Financial Risk.—We note that the Epsom Urban District Council have been unable to raise a loan of £16,100 at 3½ per cent. for their proposed electricity works, with the result that they have decided to offer 3½ per cent.

An Automobile Race in America.—According to the *Electrical Review* of New York, a 50-mile automobile race took place recently in Long Island. There were in all nine entries, the winner proving to be an electric automobile, the only electric vehicle competing, which covered the whole distance in 2 hours 3·5 minutes.

Personal.—At a special meeting of the Council of the Society of Arts, held at Marlborough House, on Tuesday last, the Prince of Wales (president) presented the Albert medal of the Society to Sir W. Crookes, F.R.S., "for his extensive and laborious researches in chemistry and physics, researches which have in many instances developed into useful, practical applications in the arts and manufactures."

Institution of Electrical Engineers.—Before Mr. H. M. Sayers read his Paper at the meeting of the Institution on May 3, the President informed the members that the Council had, according to the Articles of Association, which allow of the election of one honorary member each year, elected Mr. J. W. Swan, F.R.S. (past president), as honorary member, and that Mr. Swan had kindly accepted his nomination.

The National Physical Laboratory.—In reply to a question in the House of Commons on Monday last, Mr. Akers-Douglas (the First Commissioner of Works) stated that the new National Physical Laboratory would be situated quite outside the Kew Gardens, on Crown lands. The building will be so placed as not to interfere with the views from the gardens of the Old Deer Park. It will be used only for delicate scientific work, which will not disturb the seclusion of the neighbourhood of the Queen's Cottage.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.

American Storage Battery Decision.—The United States Circuit Court of Appeals for the First Circuit recently declared that the Hatch battery, owned by the Hatch Storage Battery Co., was "clearly an infringement" of the Brush patents, owned by the Electric Storage Battery Co. This decision secures to the latter company the monopoly in the United States, during the life of the patent, of batteries composed of "a plate or

Digitized by Google

suitable support primarily coated or combined to a chemically-applied oxide of lead or equivalent lead compound," without which a commercial storage cell is impossible.

The German Atlantic Cable.—The laying of the shore end of the Borkum-Fayal section of the German Atlantic cable, and about 100 miles of a lighter type, was successfully accomplished by the cable-ship "Britannia," on the 4th and 5th inst. The cable steamer "Anglia" was to leave London yesterday for the purpose of joining up the shore end and proceeding direct to Horta-Fayal, so that the completion of the whole section may be expected before the end of the month. Congratulatory telegrams were exchanged between H.I.M. the Emperor of Germany and the Directors of the Company, Mr. O. Moll and Mr. C. W. Guilleaume.

Australasian Cable Position.—Reuter, under date May 4, announces that the Postmasters-General of New South Wales and Victoria have come to an agreement on the disputed points in the proposed agreement with the Eastern Extension Telegraph Co. The arrangement is made subject to the approval of the company and the ratification by the Victoria and New South Wales Parliaments, which will not meet for two months. Tariffs in the meantime will remain unaltered. The agreement now arrived at stipulates that the two Governments shall have the option of purchasing the Eastern Extension Co.'s cables. No other company is to be allowed to open offices in the colonies until after the refusal of the Eastern Extension Co. to do so.

New Water-Power Scheme in America.—According to the *American Electrician*, the Susquehanna Electric Power Co. is contemplating the erection of a power-house on the Susquehanna River, in Maryland, about three miles south of the Pennsylvania line, for the purpose of converting the power of the river into electrical energy. It is proposed to build a dam across the river above the Pennsylvania border line, and construct an embankment from this dam to the power house, where the available head will be 40ft. It is estimated that the normal flow of the river will give an output of 40,000 H.P., and that the development of the plant will cost $7,000,000. We understand that it is intended to transmit the power electrically to Baltimore and Philadelphia, where, the promoters assert, the cost will not exceed one-half of the amount paid for steam power in these cities.

Obituary.—We deeply regret to announce the death of Dr. Edmund Atkinson, F.R.S., on the 4th inst., after a very short illness. Dr. Atkinson was born at Lancaster in 1831, and was a student of Owen's College in the early days of that institution. He was for some time the assistant of Prof. Edward Frankland, after which he left to continue his studies on the Continent. On his return he became assistant to Sir Benjamin Brodie at Cheltenham College, and subsequently Professor of Experimental Science at the Royal Military College, Sandhurst, and at the Staff College. He was one of the founders of the Physical Society, of which he was treasurer until the last general meeting. He is, perhaps, best known to physical students by his able translations of Ganot's "Elements of Physics," Mascart and Joubert's "Electricity and Magnetism," and Von Helmholtz's "Popular Scientific Lectures."

Glasgow Section of the Institution of Electrical Engineers.—A meeting of the Glasgow Section was held in the Glasgow and West of Scotland Technical College on April 27, the Vice-President, Prof. Magnus McLean, in the chair. The chairman announced that, this being the annual business meeting, it devolved upon the members present to elect the office bearers for the ensuing session, and he stated that it was the unanimous opinion of the committee that with one exception the provisional office bearers (a list of whom appeared in *The Electrician*, Vol. XLIV., p. 470) should be elected *en bloc* for the next 12 months. The one exception mentioned was the case of the hon. secretary, whose duties had been so ably carried out up to the present by Prof. Watkinson, but who now found that he was unable to devote sufficient time to them; in his place, therefore, the committee proposed that Mr. E. George Tidd be elected, retaining Prof. Watkinson on the committee as an extra member. This resolution was duly approved. A letter from the president, Lord Kelvin, was then read, expressing regret that, owing to other pressing engagements, he would be unable to deliver his presidential address this session.

The Generating Machinery at the Paris Exhibition.—The daily papers contain accounts of an unfortunate *contretemps* in connection with the generating machinery at the Paris Exhibition. For the illumination of the grounds on Sunday, owing to the non-completion of a great part of the generating plant, put down for the exhibition itself, an auxiliary supply had to be obtained from outside firms, notably the Western Railway Co. The German firms who have supplied part of the generating plant within the Exhibition were, on Friday, reported to have refused to start their machinery, although it was practically complete, asserting that it would be dangerous for the machinery, on account of the dust and dirt from the building operations in other parts of the same section. It appears, however, that notwithstanding this, some at any rate of the German machinery was put into operation but that the bearings of one of the 1,500 H.P. sets siezed. A statement has been made that gravel was wilfully placed in a lubricator, which was closed by two special screws, and the police are, it is said, investigating the matter, suspecting that one of the workmen engaged is the culprit.

Destruction of a Large American Power Dam.—The *Western Electrician* of Chicago reports the destruction, on April 7th, of the large dam which was built across the Colorado River at Austin, Texas, and furnished power for the municipal waterworks, electric light, and power plant of that city. A few days of heavy rain had caused the rapid rise of the river, the flood bringing with it a large quantity of wreckage. This mass bore too heavily on the dam, and finally broke out a section in the centre 25ft. high, 500ft. wide, and 8ft. thick. Above the dam was Lake McDonald, 25 miles long, 60ft. deep, and covering an area of 2,000 acres. This great mass of water poured through the break, destroying the power house just below the dam, drowning seven employés, and then swept through the city and down the river. The flood caused great destruction to life and property in Austin and for 200 miles below the city; 48 persons are known to have been drowned and seven missing, while more casualties are expected to be reported later. The damage to property is estimated at nearly £2,000,000. The dam which was wrecked was begun in 1890 and finished in 1893 at a cost, with the power house, of £290,000. It was built to take 15ft. of water over its crest. The total length of the dam, including bulkhead and headgate and a weir of 1,090ft., was 1,360ft. The width of base was 66ft. and the total height above the foundation was 68ft. The power house was equipped with turbines having a capacity of 5,000 H.P. Seven iron penstocks, each 9ft. in diameter, conveyed the water to the waterwheels. Four of these penstocks were used by the city for its electric light plant and waterworks, while the others were used by private manufacturers. As a result of the destruction of the dam and power house the city will probably be forced to remain without light and water for some time.

The Economical Disposal of Town Refuse.—At a meeting of the Society of Engineers, on Monday, May 7, a Paper was read on "The Economical Disposal of Town Refuse," by Mr. Brierley Healey. The author first referred to the imperfect results obtained with the methods of refuse disposal formerly adopted by sanitary authorities. He then explained the procedure to be adopted in the selection of suitable plant when the requirements of the case were known. The capital outlay and working expenses of various systems were dealt with in an elaborate table of results. The author then showed the great loss of calorific value when too many furnaces were connected to one steam boiler. The general arrangement of modern plant, the height and size of stacks, the dimensions of main flues, the pressures for forced draught, and the temperatures of furnace gases were then considered. The author observed that

Digitized by Google

when using natural draught the temperature of the flue gases was considerably less than when using forced draught, the latter requiring about 2lb. of air per pound of refuse burnt, or say about 485 cubic ft. per minute, for a consumption of 10 cwt. per hour, whereas double that volume of air was usual for natural draught; hence the lowering of the temperature in the flues. The volume is doubled by an increment in temperature of 485°F., so that whether using forced or natural draught the same size of flues is necessary. The use of screened *versus* unscreened refuse was then discussed, the results, as stated, being in favour of the latter. Considerable stress was laid upon the importance of following up in practice every operation with regularity, particularly in charging and clinkering the furnaces. In conclusion, the author outlined what he considered might probably be the type of steam generator for future destructors. It may be termed a vertical water tube boiler set between a pair of furnaces or between two ranges of flues, the circulation being so arranged that all deposit would be thrown down in the upper drum.

A Balanced Multipolar Armature-Winding.—A recent number of the *Electrical Review* of New York describes the winding of the armature of a multipolar railway generator, the special feature of which is claimed to be the balanced condition of the magnetic circuits. Some difficulty is frequently experienced in the operation of large multipolar direct-current machines with parallel-wound armatures, owing to the difficulty of securing the same magnetic flux at all the poles. The potential generated in the conductors under one pole sometimes differed from that under another similar pole, and thus gave rise to waste currents between the brushes and between sections of the armature-windings. This difficulty is obviated by the following method of balancing. A number of points in the armature winding, which are normally of equal potential, are connected by leads through which currents may pass from one section to the others with which it is connected in parallel. The currents are alternating in character and lead or lag with reference to their respective electromotive forces, and thus magnetise or demagnetise the field magnets so as automatically to produce the necessary balance between them. The method of balancing is said to be of great advantage in eliminating the sparking at the brushes and other wasteful heating which occurs when an armature runs out of truth, due to wear of the bearings or from other causes. When, on account of the armature being out of centre, the air gap on one side is greater than that on the opposite side, the potential generated in the coils on the side having the smaller air gap is considerably higher than that generated in the coils under poles of the same polarity on the opposite side; consequently a current corresponding to this difference of potential flows from one section of the winding to another through the brushes and connecting leads. The pull exerted by one side of the field on a large armature, even if out of centre by only a small fraction of an inch, may become as high as seven tons if no method of balancing is used, and would result in the heating and rapid wearing of the bearings. By proper balancing, the induction under all poles is maintained practically the same, causing the magnetic pull to be equal at all poles and preventing an unbalanced pull.

Electrical Operation of Lock Gates.—The April issue of the *Engineering Magazine* contains a brief description of the mechanical arrangements for operating the lock gates at Ymuiden, in Holland, at the mouth of the Nordzee Canal. The description is taken from a Paper read before the Netherlands Royal Society of Engineers. As a result of experiments made with hydraulic and electric systems, it was finally decided to adopt the latter system. The feature which influenced this decision was the distance separating the several sets of gates. This would have involved the use of long systems of high-pressure hydraulic piping, or three separate pumping plants, while in the case of electricity the current could readily be transmitted to all points. In addition, the electric plant could be used for lighting purposes. There existed, however, the difficulty in the case of electricity that the rapid motion of the motors had to be converted into a slow, steady movement suitable for controlling such heavy masses; also the switching devices, especially in connection with automatic operation, became somewhat complicated; and moisture was everywhere present. Each gate is operated by means of a long connecting rod, attached at about the middle of the width, the inner end of the rod being connected to a travelling carriage to which motion is given by four endless chains passing over sets of sheaves. The chain sheaves are operated by a train of gearing driven by the electric motor, the speed being reduced by a worm wheel and pair of worms. The motor in each case is placed in a separate chamber from the rest of the mechanism, this room being carefully cemented to prevent the access of moisture, the motor shaft passing through a fitted bearing in the wall, and there being three doors in the passage communicating with the chamber containing the operating gearing. There is one 45 H.P. motor for each gate, and it is required that this shall open the gate in 1·5 minutes, against a difference of level of 4in., the motion being automatically arrested at each end of the travel. In addition to the mechanism for operating the main gates, the by-pass gates by which the lock chambers are filled and emptied are operated electrically, the whole being under the control of a single operator. The whole arrangement, including the connections, electric brakes, and wiring, appears to be remarkably well adapted to the peculiar conditions of the service, and it is probable that this installation will lead to the application of electric power to canal and reservoir locks elsewhere. The power station for the plant contains two steam engines and dynamos of 100 H.P. each, besides a large storage battery.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

(To-day) FRIDAY, May 11th.

INTERNATIONAL ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, &c.

4 p.m. Meeting at the Society of Arts, John-street, Adelphi. Prof. Patrick Geddes will deliver an Address on the Nature and Aims of the Association and its forthcoming Assembly at the Paris Exhibition.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Chemical Society's Rooms, Burlington House. Agenda: (1) Discussion of Prof. Lodge's Paper, "On the Controversy concerning Volta's Contact Force"; (2) "The Heat of Formation of Alloys, by J. B. Tayler; (3) "On the Want of Uniformity in the Action of Copper-Zinc Alloys on Nitric Acid," by Dr. Gladstone, F.R.S; (4) An Electro-magnetic Experiment and Experiments illustrating the Aberration called Coma, by Prof. S. P. Thompson, F.R.S.

TUESDAY, May 15th.

INSTITUTION OF ELECTRICAL ENGINEERS.

7.30 p.m. Students' Meeting at the Finsbury Technical College, when a Paper will be read on: "Hertz Waves and Wireless Telegraphy," by R. G. Howgrave-Graham.

WEDNESDAY, May 16th

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "A National Repository for Science and Art," by Prof. Flinders Petrie.

THURSDAY, May 17th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture IV., on: "A Century of Chemistry in the Royal Institution," by Prof. Dewar, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting at the Institution of Mechanical Engineers, Storey's Gate, S.W. Paper to be read: "Alternating Current Induction Motors," by A. C. Eborall.

FRIDAY, May 18th.

INSTITUTION OF JUNIOR ENGINEERS.

8 p.m. Ordinary Meeting at the Westminster Palace Hotel, Victoria-street, S.W., when a Paper on: "A Short Review of the Motor-Car Industry," will be read by Messrs. B. H. Joy and C. H. Rush.

ROYAL INSTITUTION.

9 p.m. Evening Discourse by Prof. J. A. Ewing, F.R.S., on: "The Structure of Metals."

Digitized by Google

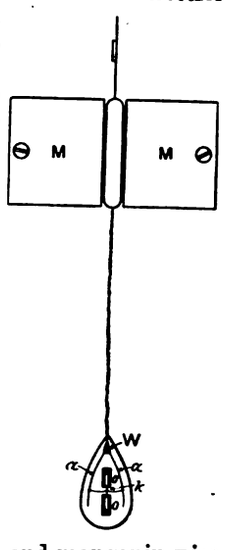
CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Maximum Sensitiveness of Coherers.—According to A. Blondel and G. Dobkévitch, the increase in the sensibility of the coherer produced by Tissot by immersing it in a magnetic field is simply due to the increased cohesion of the particles, and is therefore a purely mechanical effect. The same increase of sensitiveness may be obtained by increasing the amount of filings between the electrodes, and thus increasing the mutual pressure of the particles. When the extra quantity of filings is contained in a reservoir connected with the coherer tube, the addition may be brought about by shaking the tube, though of course this not so convenient as increasing the magnetic field, as in Tissot's contrivance. For maximum sensitiveness a coherer should fulfil the following conditions: The E.M.F. of the battery should remain below the critical value; the E.M.F. produced by the impinging waves should exceed the critical value, the current established on coherence should be below a certain value (usually 1 milliampere) if the coherer is not to deteriorate; the current which traverses the tube after a shock should be a very small fraction of the preceding current. With a given height of mast, the sensitiveness is, therefore, increased by reducing the critical E.M.F. This may be done by employing filings which are slow to oxidise, and by putting the tube into circuit with a battery of feeble E.M.F. and a relay of feeble internal resistance. The authors use a battery of 0·5 volts, and a tube with a critical E.M.F. of about 1 volt. The relay has a resistance of 100 to 200 ohms. It is even better to substitute for the battery a potentiometer connected with a battery of accumulators.

[Blondel and Dobkévitch, *Comptes Rendus*, April 23, 1900.]

Radio-Micrometer for Electric Waves.—Klemencic first made use of the thermo-junction for the measurement of electric waves. His device consisted of two thin sheets of brass, having soldered to them a very fine platinum and a very fine platinum-nickel wire respectively, which were crossed in the middle between the two strips, and thence conveyed off at right angles and soldered at their other ends to the leads of a very sensitive galvanometer. This resonating system was fixed at the focal line of a cylindrical reflector. Electric oscillations between the two strips produced heating at the knot, which gave rise to a current through the galvanometer. G. W. Pierce has combined this principle with that of Boys' radio-micrometer. The arrangement is shown in the diagram, where MM arethe poles of a horseshoe magnet. The coil consists of a single loop of silk-covered copper wire. The resonating system consists of two copper cylinders, *o o*, 8mm. long and 1mm. apart, which have a thin constantan and manganin wire soldered to their ends. The resonators are sewn on to a mica vane, and the springiness of the copper leads *a a* keeps the thermo-junction in contact. To protect the latter from radiant heat, the apparatus is cased in wood.



[G. W. Pierce, *Am. Journ. of Science*, April, 1900.]

The Arc between Metals.—For the study of the electric arc as influenced by the surrounding gas, metallic electrodes are much to be preferred to carbon electrodes. Their composition is better defined, and they do not give out the great quantities of strange gases which render experiments in different gases worthless in the case of carbon electrodes. Leo Arons has therefore studied the behaviour of the metallic arc in various gases for several years, and although he has not succeeded in obtaining any results of a precise quantitative nature, the data so far obtained yield some interesting information. Measurements were made in nitrogen and in hydrogen. In the former gas, arcs were obtained between aluminium, cadmium, copper, iron, magnesium, platinum, and brass electrodes. Tin melted at once, and between silver electrodes no arc could be made to play in an atmosphere of nitrogen. This fact is all the more strange as silver yields a particularly brilliant arc in air. It is evidently connected with the difference of chemical affinity between the metal and the gas in the two cases. The author found that nitrides are formed of all the other metals, but not of silver. Aluminium electrodes are covered with a greyish-black crust, whose chemical properties identify it with the nitride discovered by Mallet. The brass electrodes acquire a copper colour, due to the greater consumpton of zinc. As regards hydrogen, it is found that copper and aluminium, which in nitrogen give very beautiful arcs, give practically none in hydrogen. Platinum, silver, iron, and lead require very strong currents. The best hydrogen arcs are obtained with cadmium, zinc, and magnesium.

[L. Arons, *Ann. der Phys.*, No. 4, 1900.]

Mechanical Action of Cathode Rays.—The rotation of little mill wheels under the action of cathode rays was for some time regarded as directly due to the impact of projected particles, and were indeed regarded as to some extent a proof of the corpuscular theory of cathode rays. But even in vacuum tubes such rotations appear long before there is any indication of cathode rays, and they cease at exhaustions at which these rays are still present in full strength. The argument from the absence of such rotations in the case of Röntgen rays also loses its force, by the discovery made by L. Graetz that light bodies made of dielectrics show under suitable conditions very lively rotations under the influence of Röntgen rays. Radiometers do not rotate, and Neesen has shown that they even experience a retarding action, evidently due to the electrostatic forces developed by the ionisation of the air. Graetz introduces small spheres, bells, and vanes mounted on needle points into an electric field traversed by Röntgen rays. They begin to rotate as soon as the radiation strikes them, and continue to rotate while the rays continue. The direction of rotation depends upon the initial tendency—at least, in the case of non-conductors. When a pair of copper vanes are substituted, the direction of rotation changes with the direction of the rays, when the axis of rotation is normal to the path of the rays. This is easily explained by the forces acting between the negatively charged wall of the Röntgen tube and the vanes immersed in the ionised gas between the condenser plates. The latter may even be dispensed with, and so the original conditions of Crookes' rotations are approximated to. The rotations are strictly analogous to those described by Quincke in the case of liquids, and are covered by Heydweiller's theory.

[L. Graetz, *Ann. der Phys.*, No. 4, 1900.]

Electrolytic Current Records.—Lichtenberg figures have been used by Koenig for obtaining some very pretty current curves, and these curves may be vastly improved by using Buerker's new Lichtenberg powder. But the method, which might be called the electrostatic method, is only available for strong currents. Moreover, the curves are not traced under the eye of the operator, but require "development" by the powder. These objections cannot be urged against the electrolytic method worked out more particularly by P. Gruetzner, who describes in detail the various applications of the method. He uses filter paper prepared with a potassium iodide paste, which he mounts on a revolving metal cylinder, the two electrodes, consisting of platinum springs, being lightly pressed against the paper. When a continuous current is used, the anode traces a brown line, due to the evolution of iodine, while the cathode leaves no trace. When an alternating current is substituted the two electrodes make alternate traces. The frequency may be as high as 400 per second without interfering with the clearness of the traces. The only disturbing factor is a short continuance of the production of iodine after the electrode has ceased to be the anode. The intensity of the current is approximately indicated by the amount of iodine evolved, *i.e.*, by the intensity of the line. The author reproduces some beautiful records obtained in this manner. Not only are continuous and sinusoidal alternate currents

Digitized by Google

shown, but also more complicated current curves are represented, as well as the "extra-currents" of induction coils. The minimum E.M.F. required is about one volt.

[P. Gruetzner, *Ann. der Phys.*, No. 4, 1900.]

Automatic Coherer.—Last year T. Tommasina announced that a certain type of carbon coherer could be made to decohere by simply breaking its circuit. He has since found that there is a kind of carbon powder which does not even require this, but decoheres itself automatically. The kind of carbon powder in question is that used in the microphones of the Swiss telephone stations. The author introduces it direct into a telephone receiver. A hole 2mm. in diameter is drilled into a plate of ebonite. It is filled with the carbon powder and closed with plates of mica. Two German-silver wires are led in from the sides, and press against the powder, their ends being about 1mm. apart. The wire of the telephone magnet is cut and the coherer inserted. One dry cell suffices to work the coherer, the impact of each wave being indicated by a very audible click in the telephone. The inventor proposes to insert the coherer in the circuit of a Morse instrument, and so to solve the problem of the rapid transmission of wireless signals.

[T. Tommasina, *Comptes Rendus*, April 2, 1900.]

Energy of Cathode Rays.—Since cathode rays are capable of fusing such a very refractory metal as platinum, the determination of their energy is a matter of some interest. This determination is usually carried out by some calorimetric method, but the only successful measurements have so far been made with the thermo-element or the bolometer. A complication is introduced into the measurements by the fact that a portion of the cathode rays is reflected, and thus the thermo-element or bolometer does not indicate their total energy. W. Cady has therefore endeavoured to determine the proportion of cathode rays so reflected, and also the extent, if any, to which they lose their energy in the process of reflection. According to Merritt, reflection does not involve any loss of energy, but his experiments are not free from systematic objections. If i is the cathode current, V the difference of potential between the cathode and the thermo-battery, Q the quantity of heat absorbed by the latter per second, then we have, if there is no reflection, the equation $iV = Q$. But if r is the proportion of rays reflected, and r' the ratio by which the energy of the particles is diminished by reflection, then we have the amended equation:—

$$\frac{iV}{Q} = \frac{1-r}{1-rr'}.$$

The author has determined r and r^1 both by means of a thermo-battery and a bolometer. Assuming r to be 0·4 the average result would give $r' = 0{\cdot}7$. These values apply to platinum only. The cathode used was a copper cylinder cooled by a circulation of water.

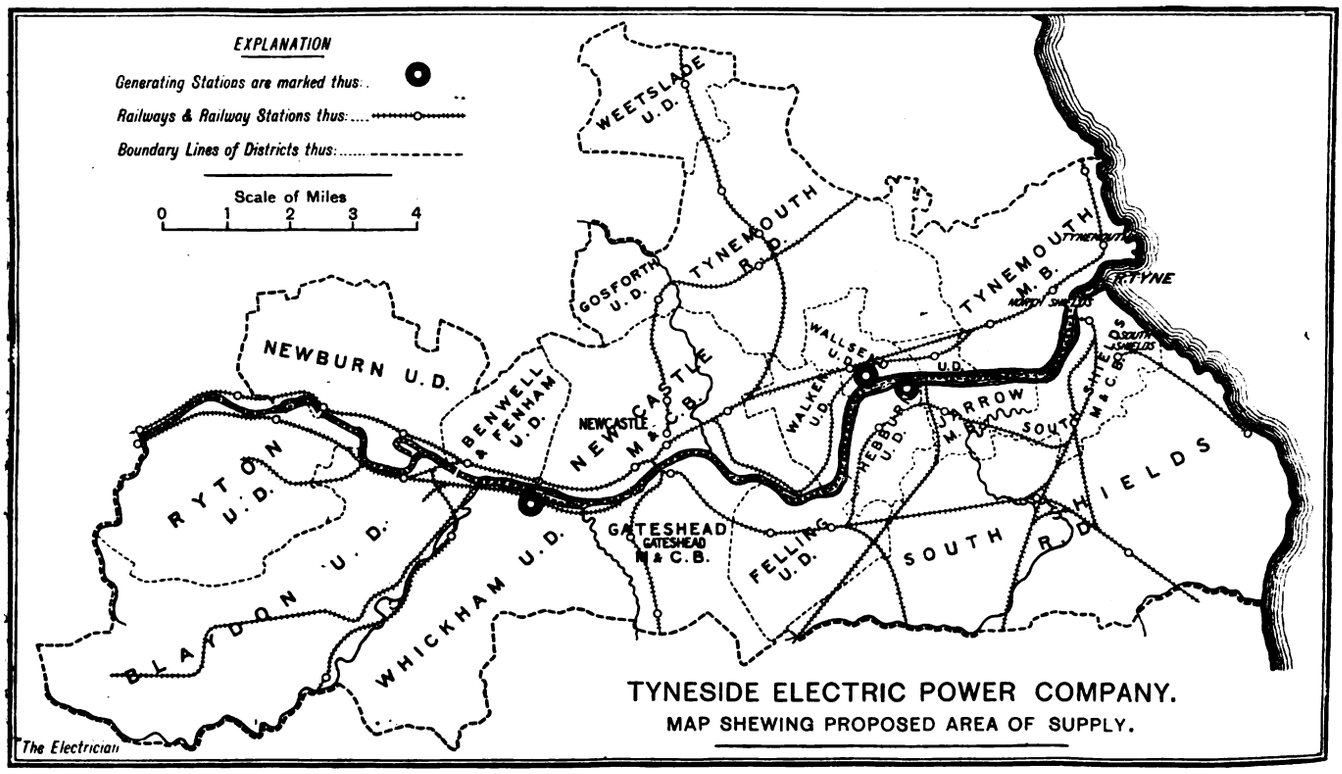
[W. Cady, *Ann. der Phys.*, No. 4, 1900.]

PROJECTED ELECTRICAL POWER SCHEMES.

(*Continued from page 59.*)

3. The Tyneside Electric Power Scheme.

The Bill promoted in the interests of this Company came before the Select Committee during the past week, and a full report of the proceedings is to be found in our "Parliamentary Intelligence" this week. The promoters are Sir William A. Noble, the Hon. C. A. Parsons and Messrs. N. C. Cookson, C. J. Leyland, J. D. Milburn, J. B. Simpson, E. Smith and A. A. Campbell Swinton. An outline of the proposed scheme is given in the opening speech by counsel for the promoters, and need not be reiterated here. The accompanying map shows the extensive area over which powers are sought to supply electricity. The area includes a portion of the area sought under the Durham scheme, as also the contentious districts of Hebburn and Felling. We deal in our leading article this week with several aspects of this scheme and of the rival Durham scheme, the map of the area for which latter appeared on page 58 of our issue last week.



Map of the Tyneside Electric Power Co.'s Proposed Area of Electricity Supply.

Digitized by Google

4. The Lancashire Electric Power Scheme.

This scheme follows the Tyneside scheme before the Select Committee. It is a much larger scheme than either of those as yet heard, as will be seen from a glance at the accompanying map. Indeed, the area of supply includes the whole of that part of Lancashire which lies to the south of the river Ribble. The map also shows the position of the four power stations it is proposed to erect on the south Lancashire coal field, which is indicated by the shaded area. The promoters are as follows, the names with an asterisk before them being also first directors:—Messrr. *W B. Hopkins, *W. P. J. Fawcus, *F. E. Gripper, *N. Scott Russell, *G. B. Samuelson, *R. P. Sellon, G. Caldwell, H. Edmunds. W. H. Edwards, M. Guthrie, F. Kitchen, R. Matthews, J. E. Prestwich, and W. W. Rutherford. The capital of the Company is fixed at £3,000,000 in £10 shares, and borrowing powers up to £1,000,000. The promoters seek to distribute power only with the consent of the local authority, and they are willing to agree that they shall not supply either in bulk or otherwise except in boroughs or districts for which statutory powers have been obtained. The profits are to be regulated by a sliding scale on a 10 per cent. basis, but the Company are to be entitled to an additional 1 per cent. above 10 per cent. for each 5 per cent. charged below the maximum rate allowed.

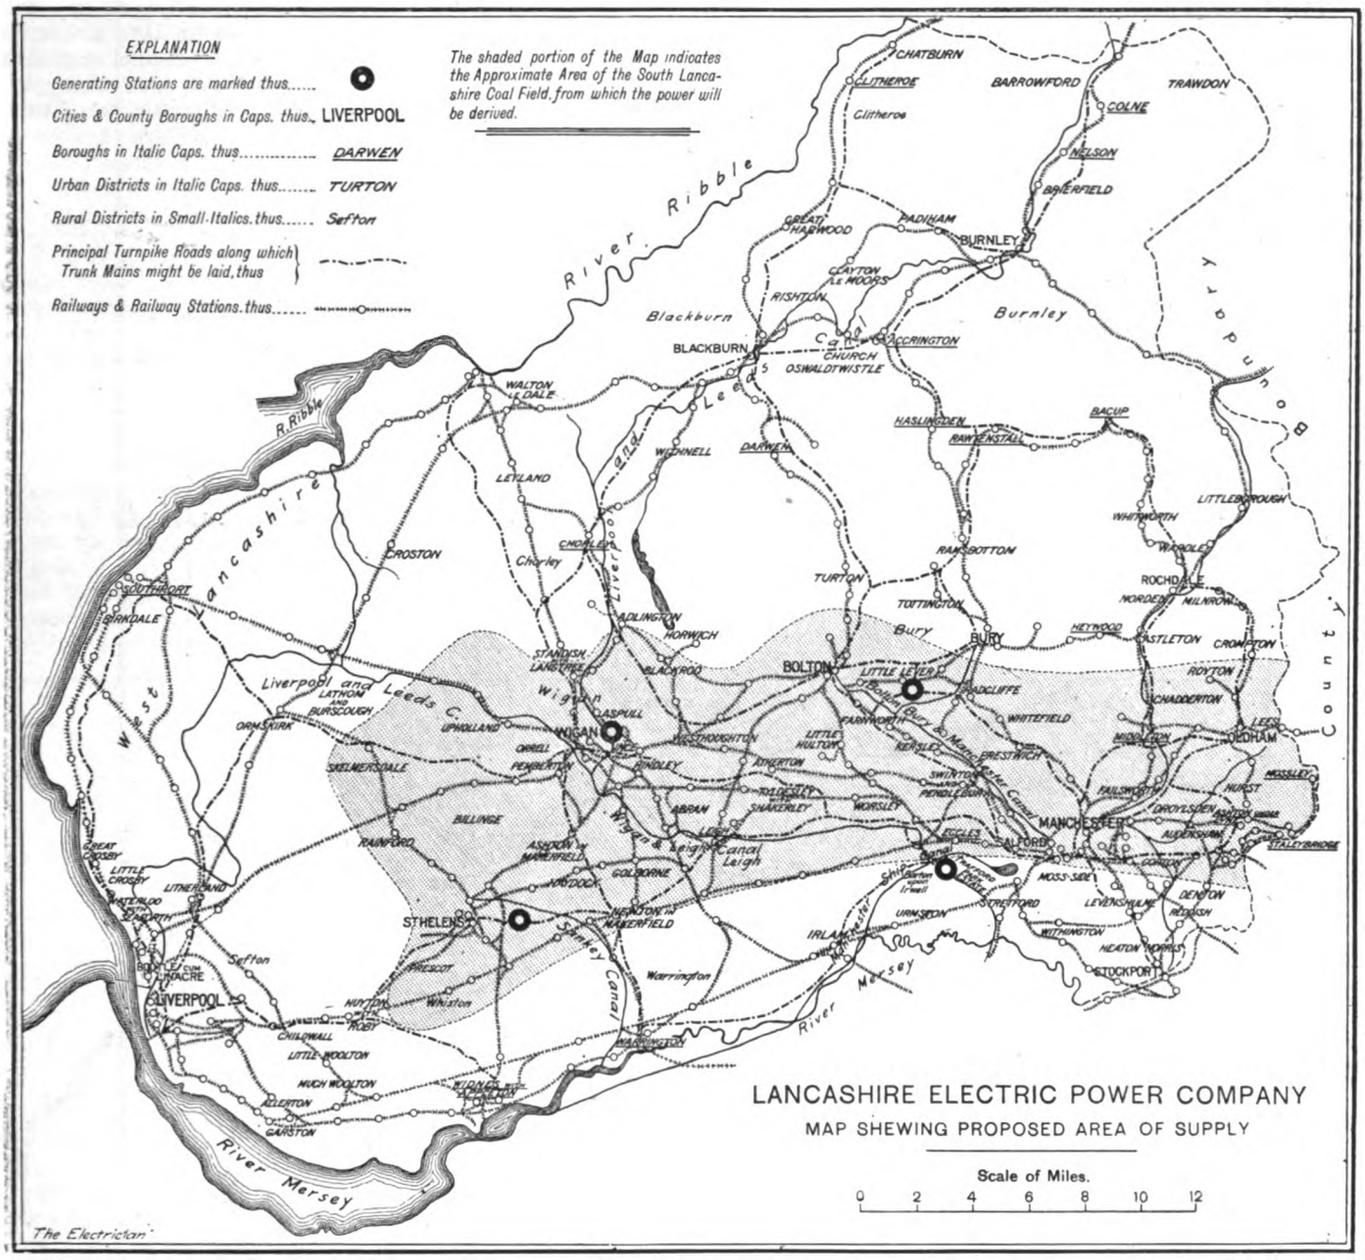
(To be continued.)

A MODERN GERMAN CENTRAL STATION.

BY JOHN R. DICK, B.SC.

(Concluded from page 45).

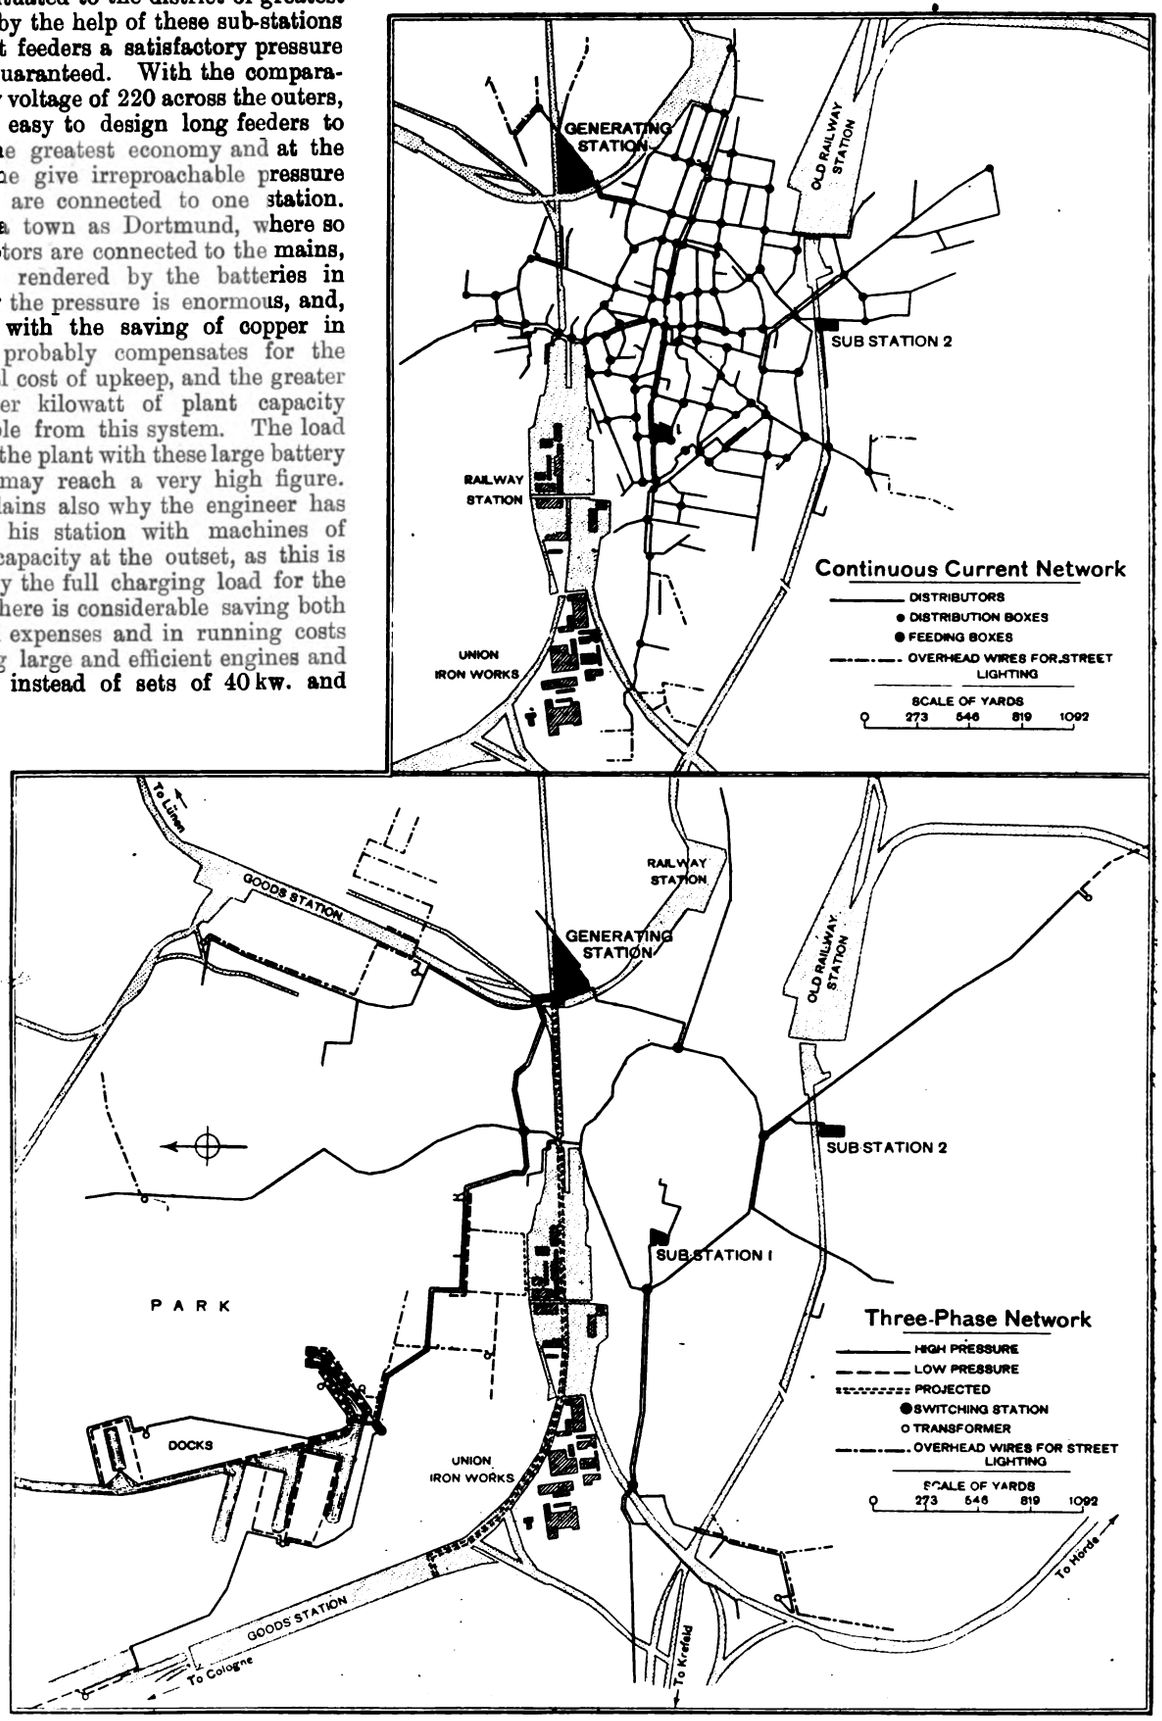
With regard to the network itself, the continuous-current distribution is arranged on the three-wire system, with 220 volts between the outers. The positions of the feeding points are shown in the plan of the mains (Fig. 4). The whole of the feeders are connected to the 'bus bars in the sub-stations, which are supplied directly from the cells. The excellence of such a system in giving uniformity of pressure is beyond dispute, as has already been amply demonstrated at Chelsea and elsewhere. It is essential to the commercial success of modern central stations to have absolute reliability of supply, and freedom from variations in the pressure at consumers' terminals. The capacities of these sub-stations are in the ratio of 8, 4 and 2 for the central station and sub-stations I. and II. respectively. From the first radiate 13 feeders, from the second 16, and from the third 9. Each group of feeders is divided into two sets of short and long, which are connected to 'bus-bars run at two different pressures. Although there is a multiplicity of feeders there is considerable economy of copper with such a method of distribution, as the maximum cross section of any



MAP OF THE LANCASHIRE ELECTRIC POWER COMPANY'S PROPOSED AREA OF ELECTRICITY SUPPLY.

Digitized by Google

feeder does not exceed 0·3 sq. in., while by far the greater number have an average cross section of only half that amount. Thus, even when the generating station is eccentrically situated to the district of greatest demand, by the help of these sub-stations and short feeders a satisfactory pressure can be guaranteed. With the comparatively low voltage of 220 across the outers, it is not easy to design long feeders to secure the greatest economy and at the same time give irreproachable pressure when all are connected to one station. In such a town as Dortmund, where so many motors are connected to the mains, the help rendered by the batteries in steadying the pressure is enormous, and, together with the saving of copper in feeders, probably compensates for the additional cost of upkeep, and the greater outlay per kilowatt of plant capacity inseparable from this system. The load factor of the plant with these large battery stations may reach a very high figure. This explains also why the engineer has designed his station with machines of 400 kw. capacity at the outset, as this is practically the full charging load for the cells. There is considerable saving both in capital expenses and in running costs in having large and efficient engines and dynamos instead of sets of 40 kw. and 50 kw.



FIGS. 4 AND 5.—MAPS SHOWING CONTINUOUS-CURRENT NETWORK AND THREE-PHASE NETWORK.

The outer wires of the network are steel armoured, lead-covered, single cables, while the middle wire is of bare tinned copper. The feeders have no middle wire, as, with so closely connected a network and an earthed neutral distributor, it is superfluous. In order to avoid electrolytic troubles, and to reduce the difference of potential between the middle wire and earth at any point, the following precautions are taken: (1) The section of the middle wire is made equal to that of the outers; (2) All the three stations are connected by special cables. The main

Digitized by Google

cables for charging the batteries are of similar construction to the distributors, and have a cross section of 0·5 sq. in. The charging leads are in duplicate to sub-station I., which has the greatest output.

The distribution for the external area, on the three-phase system, is effected entirely at a pressure of 3 × 2,600 volts without special feeders. The position of the mains is shown in Fig. 5. Single transformers are installed on consumers' premises which reduce the pressure to 3 × 120 volts. The cables are three-core, lead-covered, steel-armoured, and are laid direct in the ground. The sub-division and the fusing of each branch of main is carried out in small kiosks constructed of sheet-iron. These are also intended to be used as feeding points for the low-tension network. These kiosks where possible are much more convenient than the ordinary underground transformer chambers, as they are easier of access and offer better facilities for obtaining permanent insulation on the transformers and switching gear.

At the present moment six distinct high pressure lines are connected to the main switch-board, but provision is made for 12 in all. The farthest point to which a three-phase supply has yet been carried is four miles from the central station. On account of the extent of the area and the distance apart of the consumers it has been found the most satisfactory system to instal separate transformers in each house, but when the demand is sufficient it is intended to supply groups of consumers on a low-tension network, fed from local transformer centres.

The industrial conditions which prevail in Dortmund render a combined system of distribution with continuous and three-phase current highly suitable. In the older central portion of the town there is a greater field for light than power, and where the latter is required the maximum individual demand is not excessive. Continuous-current answers admirably for transmitting to these short distances, and the continuous-current motor is equally suitable for the usual loads. In the outer zone where the factories are situated, the demand for motive power is greatly in excess of that for lighting purposes, and necessitates larger motors than in the central area. Three-phase distribution amply fulfils these requirements, as it can go to any practicable distance with good economy, and gives the advantages of a motor which is simple in construction and easy to maintain in working order. It will be observed on the plan of the mains that, where there is an exceptionally large power user in the central area, a special service is laid from the three-phase system instead of connecting the consumer to the central current network.

The lighting of the factories is a very small proportion of the total polyphase load, and, therefore, variations of pressure are not of such importance as in the central district. No difficulty is found, however, by taking a little care in balancing the lights, in securing good results as regards pressure. The reliability of the supply and its adaptability to the requirements of the district have led to remarkable developments in the demand for motive power. Thus at the end of September, 1899, the total connected load was made up of 1,246 kw. for lighting purposes, and no less than 842 kw. for motive power. The figures showing the units sold are still more interesting and instructive. The energy consumed by the motors during the year 1899 was 660,400 units, while that for lighting was only 421,400 units. It must not be forgotten that no electricity is yet being sold for traction purposes. The curve (Fig. 6) illustrates the excellent manner in which the motor output is maintained in summer as well as winter, and how steadily the connected motor load increases from month to month. In the three-phase district the amount of electricity sold for motive power during the six months ending September, was 22 times as much as that for lighting in the same district. For the continuous-current network the motor output was three-fourths that of the lighting.

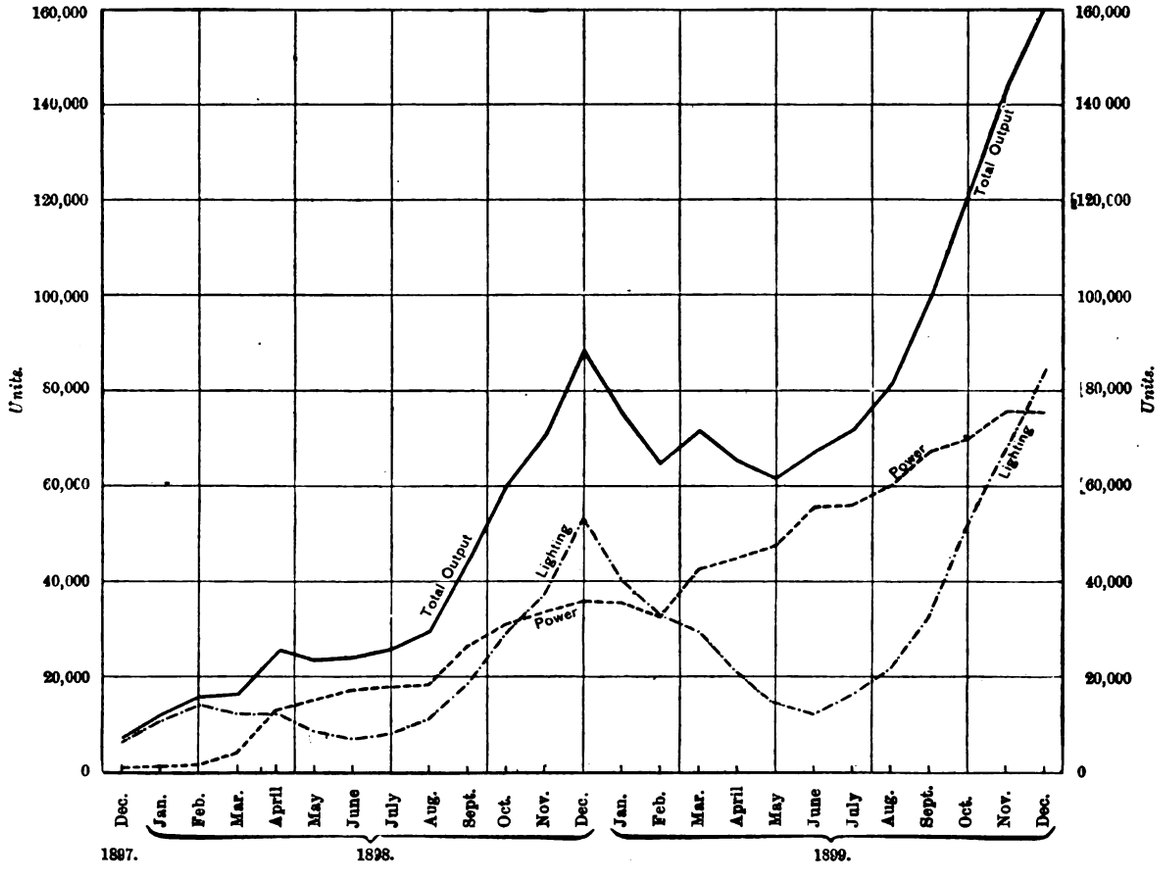


FIG. 6.—CURVES SHOWING UNITS SOLD PER MONTH.

The analysis of the consumers of motive power given in the list on page 84 shows how universal its employment has already become in Dortmund.

There were, on April 1, 1899, 93 consumers having 113 motors of a total capacity of 661·7 kw., and on October 1 these figures had increased to 148 consumers, with a total capacity in motors of 842 kw. The rapid extension of the use of motors for such a variety of manufacturing and busi-

Miscellaneous, heating, &c., including motors...	...	68·6

ness purposes is very striking, especially in view of the fact that the station has only been running for two years, and that there is no provision for the hire, or hire-purchase of motors. of space, convenience in starting, cleanliness, &c., than English consumers are. At all events a large motor load is characteristic of most of the chief central stations in Germany. In Berlin, for example, no less than 8,000,000 units were sold for general motive power last year, while for the tramways the amount sold exceeded 10,000,000 units. The sale of electricity to motors is strongly encouraged in Dortmund, and the business is developed by every possible means. The Welsbach gas burner is a formidable rival of the glow lamp all over the Continent, especially for stations just commencing supply, and in this town the rivalry is very marked. The progress of electric lighting being proportionately slow, attention is turned to the supply of electricity for power purposes, where the competition with gas is not so keen. If the necessity is not so immediate in England of endeavouring to obtain a large motor load, our central stations might surely do something more than at present to justify their dual designation of "electric light and power undertakings." The distinction of having an extraordinary demand for power is an empty one unless it is associated with corresponding profits.

At Dortmund the electricity department does not pay interest or sinking fund for the first three years, consequently a handsome surplus is shown on last year's working. The

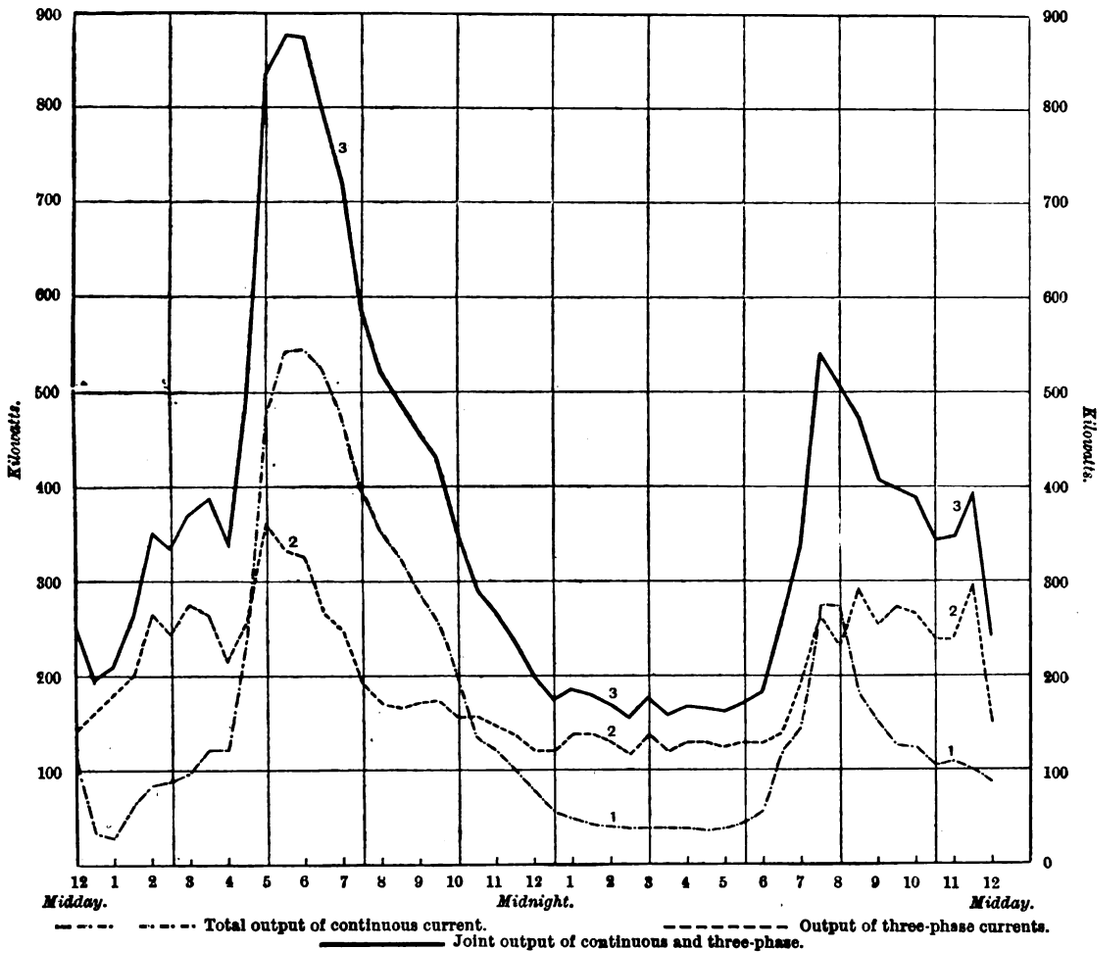

FIG. 7.—LOAD CURVES, 22ND—23RD DECEMBER, 1899.

In comparison with these results the corresponding figures of most English central stations are disappointing. In several of our largest manufacturing towns where the electric motor is the ideal prime mover for small factories the demand is less than 50 H.P. There are several conditions to be satisfied to secure success in the distribution of electric power. The principal are: (1) The current must be supplied in a form suitable for motors; (2) the supply must be absolutely reliable; (3) the price must not be too high. Many English stations fulfil these conditions admirably, yet the use of the electric motor for general factory work is very limited. It may be that the German consumers are more appreciative of the advantages of the motor in respect of working efficiency, economy prices are 6d. and 2½d. per unit for light and power respectively, with liberal discounts to large power consumers, based partly on the number of units sold and partly on the load factor of the kilowatts installed. The profit-earning character of the large motor load can be recognised by a glance at the load curve of the polyphase system, shown in Fig. 7, in which the lighting load may be practically neglected. It is remarkable how well maintained is the demand for power throughout the whole day; in fact, it is so constant as to make the average annual load factor of this class of business as much as 20 per cent. The almost exact coincidence of the peaks of the continuous and polyphase curves is worthy of notice. It is often asserted in bringing forward reasons for charging

Digitized by Google

a very much lower price for motive power than for lighting that the demand for power is essentially greatest during the day, and diminishes or ceases at the time of the lighting maximum. Such an argument is not easy to refute because there are hardly any cases where the output for power can be differentiated from that for lighting. In the present instance, where the three-phase system is practically supplying a motor load only, there can be no doubt of the falsity of such a proposition. These curves show clearly that the motor load must rank equally with the lighting load in supporting its share of the standing charges of the station. The logical result is that the tariff for motive power should be the same as that for lighting, where Wright's system is employed, since basement lights burning all day are much more profitable than an electric motor used intermittently, and ought not to be less favourably taxed. Yet a central station may foster a motor load where basements do not exist, and may find it expedient to make certain concessions to bring the price low enough to compare well with gas in gas engines. The station will then be content with a profit on the low-priced units for motive power smaller than that for lighting—say, prices of 7d. and 1d. and 7d. and 2d. respectively. This method savours too much perhaps of the policy of opportunism, and is not so satisfactory as that suggested by Claude of giving considerable "trade" discounts on the number of profitable or low-priced units, whether sold for lighting or power. These methods are at the present moment under consideration at Dortmund, and probably in the near future a tariff based on the maximum demand will be established.

The system of distribution with bare earthed neutral, introduces some novelties into the regulations for house-wiring. In any house bare wires may be used for the neutral, but these must be of tinned copper, and not less than $\frac{1}{16}$in. in diameter, and, wherever possible, must be connected to earth. The two allowable methods of installing wires are: (1) to fix them on insulators, or (2) to run them in iron pipes. Woodcasing is absolutely forbidden. The rules are very voluminous, but scarcely call for further comment, with the exception of the rule for arranging installations on the three-wire system. Each consumer having more than 1 kw. (or 9·5 amperes) in lamps installed, must divide his lamps into two equal groups and connect them to opposite sides of the three-wire system. To have such a regulation for small demands entails an increased cost to the central station for service connections, and we are not accustomed in England to enforce it for consumers with a demand less than 3 kw. On the Continent generally such a regulation as at Dortmund is usual, and necessitates installing three wires in the premises of 50 per cent. of the consumers. The balance on both sides of the three-wire system is better, and consequently the pressure is more uniform than if there were fewer three-wire services. In addition, the less the current can be made in each individual section of the bare neutral the less likelihood will there be of injurious electrolytic action. A good balance in each section is for this purpose most desirable. In the case of central stations having large supply batteries the working is very much simplified if the daily discharges on + and − sides are approximately equal. The life of the batteries is prolonged, the charging is easier and the voltage regulation is more perfect. Also it must not be forgotten that there are practically no neutral feeders, and any excess of load on one side might cause a serious drop in pressure.

I cannot conclude this description of the central station at Dortmund without expressing my appreciation of the kind manner in which the engineer, Herr Döpke, placed at my disposal his very complete data and records. To him also my best thanks are due for providing me with the photograph, plans and curves which illustrate the text.

A 1,000-Mile Electric Tramway Ride.—A lady describes, in an American daily, particulars of a trip of 1,008 miles by trolley, which was as nearly continuous as the schedules would permit. The time spent on the car was 112 hours 25 minutes, and the money spent in fares over the electric lines was $12·05. This is at the rate of 0·59d. per mile. The total length of the breaks between successive lines was 54 miles.

ON DISTANT ELECTRIC POWER TRANSMISSION.*

BY PROF. GEORGE FORBES, F.R.S.

(*Concluded from page 51*).

I now turn to the second portion of this Paper, dealing with some of the problems which I suppose have been threshed out independently by each one who has had to carry out any large transmission scheme. I wish to draw attention to Lord Kelvin's law of economy, to the use of boosters and phase rectifiers, to the relative merits of different kinds of polyphase systems, to overhead and underground conductors, and to the use of aluminium.

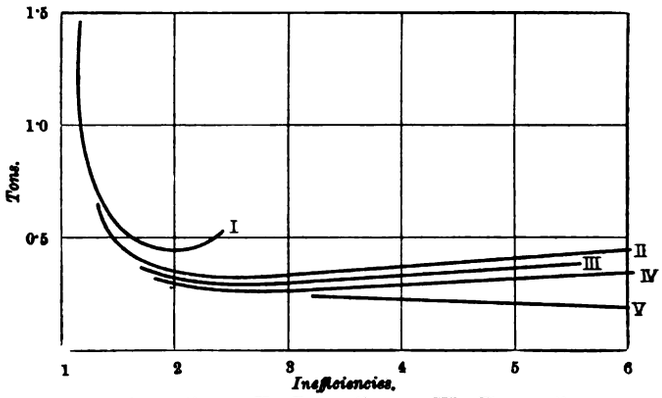
Kelvin's Law.

I should like to see an accurate volume published on the correct use and development of Kelvin's law of economy. Here I must condense. The data on which we choose our current density by this law depends on: (1) price of copper; (2) price per annum of the horse-power; (3) interest on price of copper. I desire to draw attention to the meaning of (2) and (3). When using water power which is unlimited compared with the demand, (2) is the price per annum of generating the power. When the water power is limited and the demand unlimited, (2) is the selling price of the power. If the copper be mortgaged, (3) is the interest paid on the mortgage, say 4 per cent. If the copper is paid for out of capital, (3) is the interest to be paid in dividends on the capital, say 15 per cent. I do not think that attention has been explicitly directed before to these points.

Boosters.

Lord Kelvin's law as he announced it was only true if the electric power measured at each end of the line was approximately the same; in other words, if the percentage drop in volts was small. Ayrton and Perry showed that Lord Kelvin, through neglect to notice this, was led to deduce wrong conclusions as to the economical current density to transmit power from Niagara to New York.

But by using boosters along the line the drop in volts can be corrected. Take as example an ordinary transmission line of 40 miles, in which the ohmic loss in power and volts is 40 per cent.



I.—One section. II.—Two sections. III.—Three sections.
IV.—Four sections. V.—Five sections.

Fig. 2.—Tons of Copper per H.P. Delivered. (100 miles; 10,000 volts).

Divide the line into four sections of 10 miles, with a loss of 10 per cent. in each. Now place alongside of it a booster line. At the 10-mile station increase the volts to the original amount by a booster at the expense of 10 per cent. of current. In the second section there is only 90 per cent. of the current, so if the conductor is the same sectional area throughout, the second section of the booster line may be 11 miles before losing the same as any section of the non-booster or ordinary line. The third section will have a length of $1{\cdot}1 \times 1{\cdot}1 \times 10$ miles $= 12{\cdot}1$ miles; the fourth has a length of 13·31 miles. Thus on the booster line the total loss of 40 per cent. is reached only after traversing a distance of

$$10 + 11 + 12{\cdot}1 + 13{\cdot}31 = 46{\cdot}41,$$

instead of 40 miles without boosters, and with the same sized wire. If instead of keeping the wire of constant section in the booster line we had kept the length of sections each of 10 miles, and had kept the current density constant, the sectional area of the conductor in the four sections would have been in the ratios 1·0, 0·9, 0·81, 0·729, whose sum is 3·439. The weight of copper on the booster system would be thus reduced in the ratio 3·439 : 4, while the efficiency would be 65·61 per cent. instead of only 60 per cent. without boosters; or, to put it in another way, the same loss at 40 miles would be obtained on the booster line with a reduction in weight of copper in the ratio of $34{\cdot}4^2 : 40^2$, which requires only 74 per cent. of the copper. In this example the loss in the booster has been neglected for simplicity of description, but would be taken account of in practice. If the efficiency of the alternating-current booster is 98 per cent. on $\frac{1}{10}$th of the power, the total loss in the booster is $\frac{1}{50} \times \frac{1}{10} = \frac{1}{500}$

* Paper read before the Institution of Electrical Engineers, April 26.

Digitized by Google

of the power, which may well be neglected in a general statement of results. The effects of capacity and self-induction (if alternating currents be used) have also been omitted in this description, and if not nullified the usual corrections must be made.

Table I. gives the weight of copper per horse-power and kilowatt delivered at the receiving end of a transmission line 100 miles long, with 10,000 volts at the generating end, without boosters—*i.e.*, in one section. Tables II., III., and IV. give the results with boosters when the line is divided into two, three, and four sections respectively. Corrections must be made for capacity, self-induction, temperature, and sag.

Another way of working the booster system is to add to the distance already covered a new section of the same length as previous ones, with the current density calculated by Lord Kelvin's law. In this case the cost of power must include the cost of copper up to the commencement of the new section. We may start with one section and with power costing nothing. In this case Kelvin's law gives the economical inefficiency = 2 (see my Paper before the Society of Arts, November, 1898). The weight of copper for this section per kilowatt delivered $= 4 \times 1{,}571 \left(\frac{\text{Miles}}{\text{Volts}}\right)^2$. In any other section, the nth, let

e_n be inefficiency of that section.

$1{,}571 \left(\frac{\text{Miles}}{\text{Volts}}\right)^2 c_n$ be weight of copper for section.

E_n be accumulated inefficiency of n sections.

$1{,}571 \left(\frac{\text{Miles}}{\text{Volts}}\right)^2 C_n$ be accumulated weight of copper,

(In Table VI. I call c_n and C_n the copper factor.)

Then, $e_n = 1 + \frac{1}{\sqrt{c_{n-1}+1}}$; $c_n = \frac{e_n^2}{e_n - 1}$

$E_n = e_1 \cdot e_2 \ldots e_n$; $C_n = e_n C_{n-1} + c_n$.

Table VI. gives the values of these quantities for 24 sections of equal length, uncorrected for capacity and self-induction.

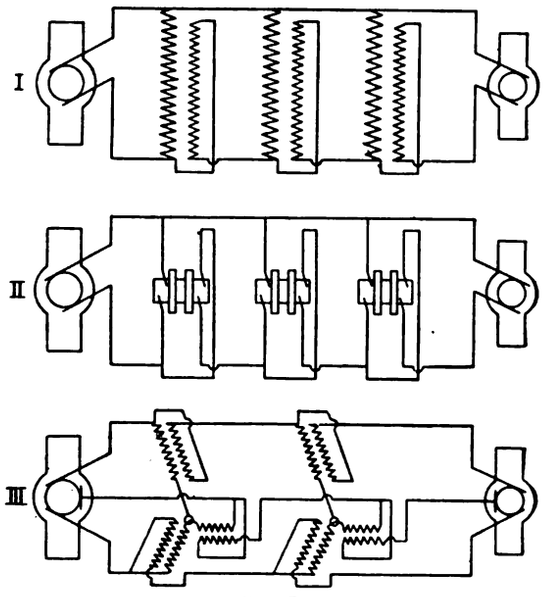


FIG. 3.

If now we wish to use this table for other cases where the cost of power is C_r, which corresponds in Table VI. to an inefficiency, E_r; then the economical inefficiency, say for eight sections, is $\frac{E_{r+8}}{E_r}$, and the economical weight of copper per kilowatt delivered is $1{,}571 \left(\frac{\text{miles}}{\text{volts}}\right)^2$. $(C_{r+8} - C_r)$. In this way Table V. has been computed.

Tables I. to VI. embody some of the best results of my study of the booster method from the year 1894 up to to-day. The curves on Fig. 2 show the tons of copper required for each horse-power delivered at different inefficiencies. It will be seen from them that by the booster method I am able to reduce the weight of copper (by putting in more turbines and dynamos) in some cases to less than one-half of what was possible by the old system.

The chief advantage of using boosters is to save copper at the cost of power generated where the latter is cheap and the distance very great. In a Paper before the Society of Arts in November, 1898,* it was shown that in the ordinary method of working there is no saving of copper when the efficiency is below 50 per cent. But if we wish it we can save copper still farther by making the efficiency still lower and using the method now indicated. Fig. 3 explains the

action of boosters: (1) for single or two phase; (2) for continuous current; (3) for three phase. I believe that Mr. Gisbert Kapp was the first to construct an alternating-current booster as here shown.

Mr. Scott, of Pittsburg, is the only person I know of who has published anything bearing on this; but his published statements are arithmetically erroneous, and so misleading, and he does not appear to have noticed the possibility of being able to save copper by reducing the efficiency below 50 per cent.

Induction Factors and Phase Rectifiers.

The low power factor of induction motors, which lies commonly between 0·6 and 0·8, must be carefully taken into account when designing any power scheme where these are used. Synchronising motors can be adjusted so as to be without either lag or lead. But they have not been so largely adopted as they might have been but for the necessity of this adjustment. The Oerlikon Co. have used synchronous motors, doing no work, in parallel with the inductive load to furnish what has been called the wattless current. In this case the synchronous motor is excited so as to act as a condenser, and is placed at the receiving end of the line. There are other methods by which idle synchronous motors may be used to overcome self-induction, and this becomes an important matter in long-distance transmission.

The self-induction of the line has to be taken into account, and I would have added to this paper the tables necessary for working out all the effects, and which I have used for many years, were it not that this would alter the character of the Paper. Table VII. has been inserted, however, to give some notion of the magnitude of the effect, and it shows at a glance the factor by which the ohmic drop of volts must be multiplied in order to give the true drop due to induction and resistance, with different frequencies, and with different diameters and distance of wires, with single phase. Distance of transmission does not affect this factor. I ought to state that an American wire gauge is used in Table VII. only because the table was completed when I was working in the United States on the Niagara scheme.

When dealing with parts of the world free from telegraphs and telephones, the beginner is apt to lay undue stress on the advantages of using an earth return with single or two-phase transmission, and overhead wires. So soon as he calculates the effects of induction he generally finds that the benefit is not what he thought. Take the case of the Niagara-Buffalo line, with cables 0·6in. diameter and 30ft. above ground, and using a frequency of 25 cycles per second. The impedance is the same as with similar cables (go and return) 60ft. apart and the factor is prohibitive.

Choice of Polyphase Systems.

In choosing a polyphase system, we may use two-phase, or three-phase star, or three-phase mesh. Three-phase star cannot well be used if any consumer's plant uses only one-phase, as was proved from actual trials in a Paper I read before this Institution in 1893.† For these cases two-phase or three-phase mesh must be used. Three-phase mesh subjects the transformers to 1·7 times the electric pressure experienced by three-phase star, or two-phase, each earthed at the centre of the electric system. The principal advantage of the two-phase is that the two circuits may be electrically disconnected, either always or else during tests. This facilitates the detection of troubles and gives far greater security, as I have convinced myself beyond doubt in actual practice.

It has been generally assumed that, using the same electric pressure, the three-phase system uses only three-quarters of the copper required for the two-phase. This is founded purely on the convention adopted in defining the electric pressure. In Fig. 4 a three-phase star and a two-phase system are represented, each with 10,000 volts between any one wire and the middle of the electric system, which may be conveniently earthed; and the two systems represented require the same weight of copper to give the same effect (though not the same number of insulators). The volts between neighbouring wires in these cases are 17,320 with the three-phase, and 14,142 with the two-phase; yet the convention is to speak of these cases as being 17,320 with three-phase, and 20,000 with two-phase. This might be an unobjectionable convention if the trouble arising from high electric pressure was due to risks of sparks passing from wire to wire. I doubt if anyone with practical experience of the troubles that do arise could support this view. Nine-tenths of the troubles come either from accidental or malicious short circuits, or else from leakage of two conductors to earth. The former cause produces a breakdown in any case. Hence leakage to earth is the only factor to be considered in this connection, and in the cases shown in Fig. 2 the

Digitized by Google

security, as measured by electric pressure on insulation, and the weight of copper, are the same for three-phase and for two-phase.

Overhead and Underground Conductors.

The choice between bare overhead conductors and insulated cables underground has generally to be decided upon considerations other than economy or effectiveness. In this country insulated cables will generally be employed. In this case self-induction of the line, which we know how to compensate in any case, can be got rid of. But the effects of capacity, which are more troublesome to deal with, are much increased. The electric pressure to be selected on an underground transmission depends almost entirely on the financial side of the question regarding relative costs for insulation. The Rheinfelden plant was the first case where the electric pressure was selected solely with a desire to obtain the best economy. In almost all other cases the pressure has been chosen by rules which depend on the timidity or rashness of the engineer, and occasionally on his past experience. We have not yet reached such pressures as require account to be taken of electric air-convection or brush discharge from surfaces of small radius of curvature, except for temporary experiments.

Aluminium Conductors.

A few words must be said about the use of aluminium as a conductor. The weight of aluminium required is almost exactly one half of the copper which would produce the same effect. The diameter of cable is 28 per cent. in excess of one made of copper, and the cost of insulation for an underground cable is increased in about the same proportion when we pass from copper to aluminium.

Aluminium is not a pleasant metal to deal with, but its high conductivity will make it invaluable for overhead transmission. It is true also that the weight to be supported on posts is half of copper, but the surface exposed to the wind is greater, and its strength is not great. The chief drawback to its use, especially overhead, is its liability to become rotten. This defect does not exist if the metal be pure and especially if free from sodium. But exposure to the atmosphere, especially near the sea, induces deterioration. The fact that aluminium is easily oxidised ought not to condemn it. The same is true of iron and steel, and yet we do not hesitate to place structures of these metals in exposed positions. Only we paint them; so I propose that we paint or varnish our aluminium conductors wherever necessary. We have had little experience in this direction. I laid out a few hundred yards of ¼in. aluminium wire on a Scotch estate a year ago, and am watching the effects of weather.

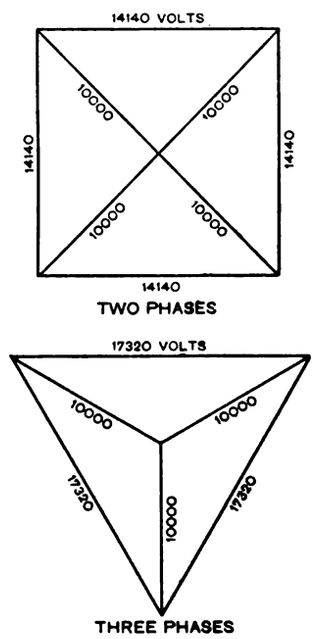

Fig. 4.

Having now dealt almost entirely with the work of foreign manufacturers, I should like to suggest that a British type of power transmission might be worked out differing in some details from what is becoming the normal arrangement. But it would be an impertinence on my part to appear to suggest to manufacturers how best to look after their own interests. The reason why I venture to broach this question is that I notice in the many tenders that come under my notice for power transmission a tendency to crystallise the proposals, and to settle into grooves which do not seem always to be the best. This stereotyped character has lately forced itself on my attention in connection with the proposed Mysore development of water power, and electric transmission over 90 miles. I received five tenders from the firms most experienced in this work in Europe and America. The most remarkable feature was their great resemblance to one another except in certain details. They all used three-phase alternating currents generated at an electric pressure between 2,000 volts and 3,000 volts. The units varied from 1,000 H.P. to 1,333 H.P. Three used mesh connections, and two used star connections. The frequency varied from 25 to 40. All used separate turbines for exciters. All had turbines and dynamos on the same horizontal shaft. The electric pressure used for transmission varied from 23,800 volts to 30,000 volts. Three preferred oil cooling for transformers, one air-blast, and one natural ventilation. The line construction varied considerably, so did the working of the distant transformer station. It is not desirable to go further into details, but it may be said that in every case two complete and independent sets of conductors were proposed. Also the loss allowed on the line was not determined by Lord Kelvin's law, but generally on the basis of enabling the proportioning of volts to load to be capable of adjustment without altering the speed.

Most of the arrangements now mentioned are admirable, and their similarity shows that there is a consensus of opinion in their favour.

I would suggest as subjects worthy of your consideration the following points:

1. The arrangement which suits a transmission line which is also a distributor of power does not necessarily yield the best results for a plant transmitting the whole power to a long distance.
2. The high-pressure continuous-current system is very suitable for certain cases, as worked out at Genoa.
3. The two-phase alternating current is to be preferred over the three-phase in many cases, and especially where an earth return can be used.
4. The horizontal shaft for turbine and dynamo which is so much in vogue, might well be replaced by a vertical shaft, as at Niagara, Rheinfelden, and other places.

I should like to mention other matters, but do not consider the time opportune. Some, no doubt, will be spoken of during the discussion, and any remarks from others who have had experience of these matters will be of value. Most of what has been said in this Paper has reference primarily to cases where water power is used, and generally to countries where bare overhead conductors are permitted. But generally the same considerations have a bearing upon cases where the power is generated by steam and where the cables are underground, although the distinctive characters of the two cases are very marked. With insulated cables the cost of insulation takes away from the superiority of two over three phases except perhaps when a common return is used. The same cause acts against the use of aluminium in place of copper underground. Again, in cases of generating power at the coal pits, the transmission line generally becomes also a distribution line and militates against the use of known methods for increasing the power factor. But the most important difference between an underground and an overhead transmission must be noticed—viz., that induction in one case, and capacity in the other, is the trouble that demands the most careful attention.

It has been my desire in this Paper to disclaim all idea of teaching the members of this Institution anything about their profession. This is not a class room. The object of this Paper is only to put down a few of the ideas about electric transmission that have occurred to me in practice during the last ten years, and which seem to be the most important at this date to draw attention to, and to ask other men of experience in this work to tell us some of the results that they have obtained.

LEGAL INTELLIGENCE.

Jandus Arc Lamp and Electric Co. (Ltd.) v. Johnson.

In the Chancery Division on Friday, Mr. Justice Farwell commenced the hearing of this action, which was for an account of royalties due (and the recovery of the amount thereof) under a licence to use two patents. The defendant, who counterclaimed for damages, pleaded, *inter alia*, that the articles he had made would not, even had there been no licence, have been infringements of the patents.

Mr. Moulton, Q.C., M.P., Mr. T. Terrell, Q.C., Mr. J. G. Graham, and Mr. A. J. Walter appeared for the plaintiffs; and Mr. Bousfield, Q.C., M.P., and Mr. J. Hunter Gray for the defendant.

Mr. TERRELL, Q.C., in opening the case, said that the licence to the defendant was dated March 24, 1898, and it was a licence to use two letters patent, No. 15,479 of 1893 and No. 437A of 1895. The substantial defence was that the goods produced by the defendant were not made under the licence and would not, if there had not been a licence, be infringements of the patents, and that no royalties were due in respect of them. The defendant also set up an extensive counterclaim for misrepresentation and for rescission of the licence.

Mr. BOUSFIELD raised a preliminary objection. What the defendant said was that at the time of the licence the plaintiffs did not possess the patents sued on and they were not mentioned in the licence. The plaintiffs said that if they made that representation or warranty, the patents were in fact the controlling patents, and that the plaintiffs became possessed of them shortly after the date of the licence. The defendant pleaded that the plaintiffs did not own those two particular patents at the date of the licence.

Mr. TERRELL (continuing) said that the patents were for arc lights, and the invention to which they referred was this: If one could enclose the arc in an envelope closed at the bottom, and the operating carbon, that was to say the moving carbon, coming in through an aperture at the top, and being almost sealed so as to prevent the circulation of air as much as possible, they got such conditions of things inside, such an intensely heated atmosphere within the glass envelope, and such a difficulty for oxygen to enter into the glass envelope and so consume the carbon, that they increased the life of the carbon from a few hours up to something like 200 hours. That was the invention, and all lamps which were used now practically involved the use of this invention. When the

Digitized by Google

licence was granted the plaintiffs were possessed by assignment of the patent No. 437A of 1895. Then they had an agreement to buy patent No. 15,479 of 1893. The defendant's licence stated that in consideration of a royalty of 5s. for every lamp made by the licensee the licensors (the Jandus Arc Lamp and Electric Co., Limited) granted to the licensee full authority to make use, and vend enclosed arc lamps, for which the Jandus Co. possessed controlling patents, in so far as related to the enclosing of the arc in two or more globes, or the equivalent. The licence was to last during the term of the patents. The licensee was to affix on a conspicuous part of every lamp which he manufactured a royalty plate, furnished by the licensors, bearing a reference number and the inscription "under licence to Jandus patents." In the event of the licensors failing for a period of twelve months, after their attention had been called to the matter, to take proceedings against parties who made use of or sold arc lamps which were infringements of the patents, the licencee should be relieved of further obligation to pay royalty. The licensors undertook that they would not grant any licences to use the patents covered by the defendant's licence at a less royalty than that agreed to be paid by the licensee without making a corresponding reduction in the royalty to the licensee. He drew his lordship's particular attention to that, because defendant said that the plaintiffs or one of their officials had made a misrepresentation, and that the defendant had, acting on the faith of that misrepresentation, taken the licence. The suggested misrepresentation was that the plaintiffs had granted to somebody a licence upon better terms than those given to the defendant, and the better terms that the defendant complained of were that the plaintiffs had granted a licence to somebody, not at a less royalty, but for a shorter period, and that the persons to whom this better licence had been granted, if the licence were determined at a shorter period of time than the whole length of the patent, might thereafter dispute the validity of the patents, that the licence applied to all forms of double enclosure except that made with the particular arrangement adopted by the Jandus Arc Lamp and Electric Co.—viz., a fixed outer globe closed at the top and the inner globe removable through valve at the bottom—that was, at the bottom of the fixed outer globe. What the defendant was therefore licenced to do was to make every form of lamp with double enclosures with a single exception. The licence further stipulated that nothing contained in it should confer upon the licensee the right to use the carbon-feeding mechanism as described in the licensors' patents, and further that the licensee should not during the continuance of the licence nor at any time after the determination thereof dispute the validity of the patent on any ground. There was no question as to the plaintiffs title regarding number 437A of 1895. Then there was the agreement of March 23, 1897, made between the Electric Arc Light Co. and the Jandus Arc Lamp and Electric Co., which recited that by an indenture of assignment dated March 18, 1897, William Phillips Thompson (one of the parties) had assigned, at the request of the Electric Arc Light Co., Thompson's patent No. 207 of 1896 to the Jandus Co., and also recited that the Electric Arc Light Co. claimed to have certain rights in the patent known as the Howard patent (No. 15,479 of 1893), which rights the latter company believed to be the absolute right to ask for an assignment of the said Howard patent. It turned out afterwards that they did have that right. In addition to the £2,500 to be paid by the Jandus Co. on the signing of the agreement, they also agreed to pay to the Electric Arc Light Co. £1,500 further upon the latter company assigning or obtaining an assignment to them of the Howard patent. That assignment had been made, and the £1,500 paid. That document was dated March 23, 1897, and was therefore a good deal in advance of the licence which was dated March 24, 1898.

Mr. Justice FARWELL: What is the date of your assignment?

Mr. TERRELL: April 27, 1898. There was an antecedent assignment with the Electric Arc Co.

Mr. BOUSFIELD said that the point was, had the defendant on March 24, 1898, a licence under the patent of 1893?

Mr. Justice FARWELL: What you are granted is a licence for all the lamps for which the Jandus Co. possessed the controlling patents. Did they possess controlling patents?—They did in equity, because they had the contract.

Mr. TERRELL, resuming, said that under the licence the licensee was not bound to do anything. If he did anything, then the plaintiffs had to establish that he had done it; and if they did so, then they were entitled to an account of royalties. The patent of 1893 was the more important, but if they got the defendant within one, that would be enough for the purpose. The specification of No. 15,479 of 1893 was entitled: "Improvements in Electric Arc Lamps," and the sixth claim was for "an arc lamp having its arc enclosed in a transparent or translucent envelope, closed air-tight at all points below the arc, and provided with a plug at the top having a closely-fitting feed opening for the positive carbon." That was one of the things the defendant was licensed to do, and he (Mr. Terrell) would show that he had done it literally. Then there was a curious defence, to the effect that he did not want to dispute the validity of the patents because, being a licensee, he could not do so; but he would produce specifications against the plaintiffs, and he devised this scheme of quoting specifications, and said he would do so by way of construction, so as to limit and reduce the scope of the patents. But in Clark *v.* Adie it had been decided that they could not do that.

Mr. Justice FARWELL: It seems to me to be an indirect way of allowing a licensee to attempt the impeachment of the patents.

Mr. TERRELL submitted that the defendant had acted under this patent, and was estopped from questioning its validity. Then, with reference to the twelfth claim in the specification, the plaintiffs said that the defendant had also taken that. It was "an arc lamp, having its arc enclosed within a transparent or translucent envelope, an auxiliary transparent or translucent envelope, closed on all sides surrounding said arc-enclosing envelope, and feed openings in the envelopes, whereby the two sides of the arc-closing envelope are maintained at a comparatively uniform temperature, and fracture is avoided." The first claim was limited to the claiming of a combination of a transparent envelope provided with certain things. The twelfth claim dealt with two enclosing envelopes, one within the other. The defendant had taken both. Then, with regard to patent No. 437A, the claim which the plaintiffs said that the defendant had taken was claim 1: "In an arc lamp, prolonging the life of the carbon by enclosing the arc within two or more chambers, so arranged that the upper part of the outer chamber is made air-tight or nearly so, while the lower part permits some communication with the outer atmosphere, and the inner chamber permits a limited communication between its interior and the gaseous contents of the outer chamber or chambers, the combination of the chambers being so devised as to surround the arc with inert or non-oxidising gases and prevent or minimise the access of the oxygen of the air to the carbons as herein set forth."

Mr. Justice FARWELL: Does that differ from the other one; is it not the same thing very much?

Mr. TERRELL said it was practically the same thing, but with improvements. But he wanted, if he could, to avoid going into any science in this case. What the plaintiffs had done was that they had bought one of the lamps which the defendant had made.

Mr. DUGALD CLERK said patent No. 15,479 of 1893 was for an arc lamp. It had its arc enclosed in a transparent or translucent envelope and was closed air-tight at all points below the arc. It was provided with a plug at the top, having a closely-fitted feed opening for the positive carbon. The lamp had an auxiliary transparent or translucent envelope closed on all sides, surrounding the first arc-enclosing envelope. There were feed openings in both envelopes. By means of these feed openings, the two sides of the arc-enclosing envelope were maintained at a comparatively uniform temperature, and fracture was thereby avoided.

Mr. MOULTON: Look at Patent 437A of 1895. By the user of that lamp, is the life of the carbon prolonged by enclosing the arc within two chambers so arranged that the upper part of the outer chamber is made air-tight or nearly so?—That is the only point on which I cannot be quite certain. In this particular lamp—the defendant's lamp—the outer globe is so arranged as to retain the inert gases, the non-oxidising gases, to a large extent; but there is an opening at the top. It is made tighter at the bottom, and there is an opening at the top, but not in my opinion, a sufficient opening to prevent the inert gases surrounding the inner globe.

Mr. MOULTON: May I put it in this way? You consider it is nearly air-tight?

WITNESS: I think not, in the sense of air-tight. There is a great freedom of opening, but not sufficient to prevent the gases accumulating.

Mr. MOULTON: Is it sufficient to accomplish what the patentee describes in his first claim?—That is my view. The object of the patent is to get inert gases surrounding. In addition to keeping the inner vessel free from fracture, the object is to have inert gases surrounding the carbon. In other respects it complies with the description of claim 1 in No. 437A of 1895. The holes outside the cap of the outer globe of the lamp left it open, but there was a masking cap on the top which choked it considerably and restricted the outflow. There was no free circulation.

Mr. BOUSFIELD: This is a patent for "Improvements in Electric Arc Lamps"?—Yes.

Mr. BOUSFIELD: Now, let me direct your attention to four specifications for lamps of a similar type of which this is the improvement—Brewer, 3,713 of 1882; Lake, 5,050 of 1882; Beardsley, 265,737 of 1882; and Justice, 7,962 of 1884.

Mr. MOULTON objected. The Court had here to construe a document. A patentee might claim a thing which was old, and he ran the risk of his patent being challenged and found invalid, but a licensee could not challenge it. In the case of a licensee it was a mere question of construction, and the clause in the patent here was without any ambiguity at all. There were no terms of art in it.

The objection having been sustained,

Mr. BOUSFIELD: Now, Mr. Clerk, go back to page 1 of the plaintiffs' specification at line 16: "It has heretofore been proposed to enclose the arc in an air-tight envelope, but all such efforts have, so far as I am aware, resulted in failure"?—Yes.

In your view I suppose you agree that that would be the case, as he states: "If the opening through which the carbon feeds is made sufficiently large to admit a very free transit of the carbon through it, ingress of air is permitted which increases the rapidity of consumption of the carbon"?—It would be so, no doubt.

Mr. BOUSFIELD: Then at line 25 he says: "With my construction these difficulties are overcome?"—Yes.

As regards this particular difficulty I am speaking of, does this arrangement overcome it: "By making the feed opening a comparatively close fit around the carbon, and providing a valve or trap for the escape of heated gases when the tension becomes sufficient to endanger the envelope, the life of the carbon is prolonged to an extraordinary degree." Is that a fact?

Mr. BOUSFIELD: Now here is our lamp, and here is the hole at the top. I put it to you that that comes within the case that he puts—which he says results in failure—if the opening through which the carbon feeds is made sufficiently large to admit a very free transit of the carbon through it, and not within the case he puts, where the feed opening is a comparatively close fit around the carbon, and he has to provide a barrel or trap to provide for the escape of heated gases.

The WITNESS, having examined the portion of the lamp, said it was a very fair fit of the carbon. It was a long passage and a good fit.

Digitized by Google

That carbon is supposed to be, I think, the accustomed size, 13 mm., and their lamps are extended for that size?—Yes.

I put it the hole is 14 mm. at the top, and 15 mm. or 16 mm. at the bottom?—That may be, but still it is a fair fit for all that.

Look at line 21, and I ask you whether this does not come within what is said here: "The opening through which the carbon feeds is made sufficiently large to admit a very free transit of the carbon through it?"—Yes.

Do not those words describe what we do in our lamp?—No, for this reason, that what he is thinking of here is quite obvious. You cannot test it in this way. You have to fix the carbon to the other mechanism of the lamp, and then it is rather difficult unless there is a wide opening to get it to move freely. This would be fairly tight when it was fixed—when the carbon is fixed, and the mechanism to which it is attached. It is not at all a slight fit. What he has here is a very narrow feed at the upper end, and it is slightly conical below. The object of that is to enable any little irregularity of the mechanism above to be adjusted, but that does not interfere with the accuracy of the fit at the entrance. What this man was thinking of at the time was what they had been doing before having very wide openings, quite a different thing to this.

Mr. BOUSFIELD: I put it to you that you are quite wrong with regard to that. First, do you admit the dimensions I gave?—I have not measured it, but I assume you are correct.

That is to say, the size of the area of the hole is 15 per cent. bigger than the area of the carbon?—Yse, that may be so. I hardly think it is in that case, looking at it.

He contrasts with that a feed opening having a comparatively close fit, and having a valve or trap provided for the escape of the heated gases?—Yes.

When you have a hole which is 15 per cent. bigger than your carbon, as you have in this case, it would be ridiculous to talk about providing a valve for the egress of the heated gases?—Quite so.

You have such a large opening round your carbon that the heated gas can get away?—You have sufficient opening there, but he includes that case simply.

At all events, he says as a method of getting over the difficulty he makes the feed opening a comparatively close fit, and provides a valve or trap for the escape of the heated gases?—That is one of his methods.

He provides a valve and a trap. I put it to you that this rod comes within the class that he says—the known class existing at the date of this specification, having an opening through which the carbon feed is made sufficiently large to admit a very free transit of the carbon through it, and not within the class where you have it packed so tight that you have to provide a valve for the escape of the heated gases?—I quite agree it is not within the class that is packed so tight as to have a valve, but I do not agree that it is within the class he is speaking of, because the opening there is not sufficiently free to do any harm. In that particular case there is not a sufficient opening to do harm.

The question is whether in what we are doing we are not doing what anybody is entitled to do, making a large opening sufficiently free for the carbon to pass freely up and down through it?—The openings before were larger than that.

Mr. BOUSFIELD, in answer to his lordship, said that he had put it to Mr. Clerk that a hole for such was in relation to the carbon as they had in theirs, was at this date a well-known thing, and when once it was known that that was the state of public knowledge you could only interpret a close-fitting feed opening as meaning one such as was here described with an asbestos lining, which made it fit so tight that you had to have a valve to let in the air.

The WITNESS, further cross-examined, said he did not remember any outside globe sealed.

Mr. BOUSFIELD: I may refresh your recollection with the meagre statement in this specification of the prior knowledge at p. 3, line 32: "I am aware that it has been proposed heretofore to operate an arc lamp in an air-tight envelope, but when the envelopes are sealed——" I think this passage is with reference to the inner envelope?—Yes.

"But when the envelopes are sealed an explosion of the cylinder is liable to result, and when not sealed a rapid consumption of carbons will result, and a smoking of the enclosing envelope." (I ought to have applied that to finish the former point.) When the envelopes are sealed then he does not want a sealed envelope?—No.

He provides a valve to let it out?—He here provides a valve or a sufficient space.

And he says: "When not sealed a rapid consumption of carbon will result, and a smoking of the enclosing envelopes?—Yes.

Again I put it to you that this is the class of envelopes which are not sealed, and which, according to him, would cause a rapid consumption of carbons and smoking of the enclosing envelope?—In a sense that is not sealed, but he gives you a case at Fig. 5, where he has done what you say.

And contradicts all he has said before, and apparently is what he has described as being the prior existing knowledge?—No. I think it is quite intelligible. I can explain it if you desire.

His LORDSHIP: I do not think it is open to you as licencee to say it contradicts all he said before.

Mr. BOUSFIELD: I have pored over this specification, and I can make neither head nor tail of these claims; they seem to be contradictory.

His LORDSHIP: You have taken a licence. It is all very well, but you are trying to make out that the patent is bad.

Mr. BOUSFIELD: No, what I am trying to show is that in doing this, which was done before the date of the patent, we are not, having regard to the knowledge and construction of the specification, making use of a globe having a hole in the top with a closely fitting feed in it.

His LORDSHIP: Assuming you proved it was done before the patent, if it comes within the words of the patent, as Mr. Clerk had said positively it does, you as a licensee would be bound.

Mr. BOUSFIELD submitted that it did not come within the words of the specification.

His LORDSHIP: Mr Clerk has said it does. At present I have only the evidence on one side, and do not see how you as a licensee can question it.

Mr. BOUSFIELD then referred witness to Clause 12 of the specification: "An arc lamp having its arc enclosed within a transparent or translucent envelope, an auxiliary transparent or translucent envelope closed on all sides." The description of lamp in Clause 12 can only be novel on the supposition that an envelope closed on all sides means an envelope completely closed on all sides?—I will not say sufficiently closed on all sides. You have his object here and he has it, in a sense closed on all sides, but if you examine minutely, in a sense he has not.

I put it, if it means sufficiently closed small on all sides, it is simply describing what was known and done before?—I do not think so.

While if it were completely closed on all sides, it may be new, but we are not doing that?—I do not agree with you. He is describing a combination there which did not as I understand exist before, and he has given the object very completely, and that object did not exist in previous lamps.

In answer to further questions as to the licences, WITNESS said the idea of a controlling patent was a patent which gave practically the control of the market.

I put it to you as a matter of fact these patents do not give you the control of the market with reference to enclosing the arc in two or more globes?—I think they do. There are many difficulties, but it seems to me they were the first people to suggest a double enclosure and I think they would be supported.

That is a matter which has to be decided by looking at the novelty of this patent.—It depends on the validity of the patents.

And depends on the state of knowledge at the date?—The validity depends on the state of knowledge.

His LORDSHIP: You cannot contest the validity.

Mr. BOUSFIELD: As a licensee your lordship sees this, that the present objection to validity comes at a point of date prior to the time of the licence. I say "you have cheated me into a position in which you have made me licensee by telling me you had got controlling patents, whereas the fact is that you had got patents which are for the merest trifles and details, and do not prevent the world at large or give any monopoly at all with regard to this manufacture." That is my position. They have induced us to put ourselves in the position of licensees by telling us they had patents. They were never named to us and we did not know what they were. We had to take it on trust from them—which would enable a monopoly of these double enclosed globes to be maintained. It turns out that the idea was quite an old one; that they can only maintain these patents for very trifling details and that they are not controlling patents, because on the then existing state of knowledge, whether this patent be good or bad, there were a number of forms of double enclosed gas lamps which were known and open to anybody to make. That is my position. All I want to succeed upon is to show that these patents are so narrow that no monopoly could be given by them at all. They are only good for something which is very narrow indeed.

Mr. TERRELL said there was a claim and counterclaim. On the claim the plaintiffs had to establish that the defendants had done something that was within the patents. On the counterclaim they claimed rescission of the whole agreement, and to claim rescission of the whole agreement would go to the root of the action on the claim as well as the counterclaim, because if the Court rescinds the agreement there is no royalty due at all.

After some further discussion his Lordship said it occurred to him that they ought to take the counterclaim first.

Mr. TERRELL felt that that would be the best plan. He wanted Mr. Clerk to go out of the box, and for his learned friend to open his claim and establish that the plaintiffs made the representation, and that he acted on the faith of that representation. When he had done that he would be entitled to call witnesses to prove the representation was untrue and there were not controlling patents, and then he would be entitled to cross-examine Mr. Clerk.

Mr. GRAY then proceeded to open the defendants' counterclaim. His lordship, he said, would notice in the recital that the plaintiffs guaranteed that they possessed controlling patents. If he could satisfy his lordship that the defendant acted upon the representation in executing the licence, of course he was entitled to rescission. But there was another ground in the amended pleadings, which he submitted was a separate ground for rescission even if he failed on that particular ground. He thought it would be desirable at the present stage to call his lordship's attention to the letter to show exactly what the plaintiffs undertook. Paragraph 5a of the amended defence said that "while the negotiations for the said licence were proceeding one Bernard Drake, acting as agent for the plaintiffs, wrote to the defendant a letter dated March 15, 1898." This letter ran: "I send you herewith the clauses accepted by the other licensees to which you refer, and trust you will now get the licence signed with these alterations—I give you my assurance that those terms are the best we have allowed to anyone, with the exception of course of the Stewart Company, who as you know were the first people." The rest of the letter was not important. That letter of March 15, 1898, was in answer to a letter dated March 10, 1898, from the defendant to Mr. Drake. In that letter defendant wrote "give me your assurance that the licence you ask me to sign is precisely the same as that signed by the other licensees." Counsel asked his Lordship to say that the intention of that paragraph in the letter of March 15, 1898, was to convey to Mr. Johnson the impression that the terms were, if not identical, the best that had been given to any licensee.

Digitized by Google

His LORDSHIP: Certainly the best, but I do not think it was intended to say they were the same.

Mr. GRAY, continuing, said that his Lordship would see that if his construction was right, if the undertaking given by Mr. Drake was one that went beyond clause 6 of the licence as regards the amount of the royalty, then any clause which enabled any other licensee at any time or under any circumstances to dispute the validity of the patent or patents was a clause better than the one the defendant had got.

His LORDSHIP: I understand your suggestion to be this—a licensee cannot dispute the validity of the patent, it is beneficial for a licensee to be able to dispute the validity of a patent, and therefore the shorter the licence the more beneficial it is, but the result of it would be: no licence, most beneficial. That cannot be the meaning of it.

Mr. GRAY said after the expiry of the licence the licensee was, of course, entitled to dispute the validity of the patent unless he had undertaken not to dispute the validity, not only during the term of the licence, but afterwards.

His LORDSHIP: Do you say that some other licensee had got a licence without the terms "nor at any time after the determination thereof?"

Mr. GRAY: I say that he had not only that, but that he had power to determine the licence within three years after the licence had been granted, and he could dispute the validity of the patent if he chose.

His LORDSHIP: Very well then, there are two points on misrepresentation: the one is as to "on best terms," and the other is as to their being controlling patents.

Mr. GRAY: Yes.

His LORDSHIP: Of course you have to call Mr. Johnson to show that he believed they were controlling patents, and that he relied upon it.

Mr. GRAY: I had better call Mr. Johnson at once.

Mr. WALTER CLAUDE JOHNSON, examined by Mr. GRAY, said he was the defendant, and traded as Johnson and Phillips. He was probably the largest manufacturer of arc lamps in the country. He entered into negotiation with Mr. Drake, the agent of the plaintiff company, in connection with the licence. The negotiations were carried on partly in writing and partly verbally. He obtained a draft of the licence some time before Feb. 9, 1898. It contained the words that the Jandus Co. owned controlling patents. The form was printed. Before signing the licence he had not seen the licences given to any other licensees. He expected that the patents were controlling patents. If he had known that the patents were not controlling patents he would not have executed the licence.

Mr. MOULTON: Your connection with the Jandus patents, both English and foreign, was a very intimate one, was it not?—Well, I think you possibly know to what extent I was interested.

His LORDSHIP said that he did not.

The WITNESS replied that he was a shareholder in the English Jandus Co. He was engaged in forming a company to work the patents in France, and was one of the vendors. He received a quantity of shares fully paid up. He did not personally see the prospectus with regard to that company. He might have a copy of it at home. The French company was formed in February, 1897. He might have manufactured 500 lamps for the English Co. The company had more orders than they could compete with, and asked witness to assist them. He knew Mr. Drake well and had gone into the matter with him and at the time of forming the company. He was aware that the company were getting the Howard patent at the time. It might be that he knew they were getting it early in 1898. He thought that Drake told him at the time they were in negotiation with a man named Marks about the Howard patent. He knew it was a question of getting it from Marks. He knew that the plaintiff company had the Barton and Jandus patents and knew they were getting the Howard. There were no others they possessed so far as he knew. He knew it was to be a combination of the Howard, Barton and Jandus patents. He was chiefly concerned in the actual turn out and sale of the lamps. He would not go so far as to say that the plaintiffs practically monopolised the market at the time. They had certainly the lion's share of the trade. He doubted very much whether they had a monopoly of the trade now. He thought they were losing it very rapidly.

Will you tell me a single big maker who is not a licensee of theirs?—I shall have to refer you to my commercial assistant. I cannot go into matters of that kind. I manufacture other things besides lamps.

Further cross-examined, Mr. JOHNSON said he could not mention the name of a single large maker of enclosed arc lamps who was not a licensee of the plaintiffs. The question whether a patent was a controlling patent or not was a matter of opinion. His cause of complaint was that his licence was not what Mr. Drake represented it to be.

Your licence was for the whole period?—Yes.

You have got all we can give you, have you not?—Yes, too much. He did grumble about having the licence given for the whole term. He wanted to be on the same terms as everybody else. The licence to the General Electric Co. was better than his because they could escape being bound by it and he could not. He of course knew what was in the document before he signed it. He had spoken to Mr. Drake about the royalty. He (witness) was concerned that no one should have a lower royalty than himself. There was a clause that the royalty should cease in the event of the patents being declared invalid by a court of competent jurisdiction.

Re-examined by Mr. BOUSFIELD: If the patents had been controlling patents it would, in his opinion, have been a profitable thing. In his view the licence was a burden to him. He thought the majority of the licensees considered it to be a burden. The General Electric licence was a licence for the full term, but there was the option to terminate it after three years on six months' notice. In his view that was a material difference. If he had known that some other licensee had a licence for a full term with an option to terminate at the end of three years he would not have signed the licence which he did sign. In his view it was an important advantage to have the option of terminating the licence at the end of three years, and if he had that advantage now he would be very well content with his licence.

After the re-examination of the witness was concluded his lordship asked Mr. Bousfield to point out the misrepresentation.

Mr. BOUSFIELD replied that he had not quite finished his evidence and called,

Mr. WUNDERLICK, who said he was formerly in the employ of the Jandus Co. but subsequently was employed by Messrs. Johnson and Phillips. He had had a great deal to do with enclosed arc lamps and became very expert with regard to the subject. When he entered defendants' employ his knowledge was at their disposal. He had himself made some inventions with reference to double enclosed lamps, and had made investigation in the field of patents and so on, and he gave defendants the results of his investigations. He first informed Mr. Johnson as to the validity of the Howard patent. He had studied that patent and compared it with others. He came to a conclusion adverse to the validity of that patent. He thought he first informed Mr. Johnson of his conclusions on the point in July or August, 1898.

This closing the evidence on the counterclaim,

Mr. BOUSFIELD said that his first point was that misrepresentation was embodied in the contract itself.

His LORDSHIP: Mr. Bousfield, may I ask you a question. Omitting the word "controlling," do you say that there is a representation that the patent is a valid patent then?—It is a grant of the use of existing patents. There is no misrepresentation there. They are merely descriptive words.

Mr. BOUSFIELD observed that a controlling patent need not necessarily be a valid patent. He pointed out that Mr. Johnson's memory with regard to the interviews and conversations was extremely weak and feeble; but he submitted he had given his evidence with the greatest fairness. At the time the licence was granted the matter was an important one to him. As a matter of fact his firm did not go into the matter of these lamps for 12 months after the licence. Messrs. Johnson and Phillips were very large manufacturers, and made a great many things, and one could quite understand that this would be a very trifling thing at the time to Mr. Johnson, and he would not try to charge his memory with the conversation which took place. The impression, however, that he got from the conversation with Mr. Drake was very clear.

Mr. Justice FARWELL said that the onus lay on Mr. Bousfield to prove misrepresentation, and he had not done so.

Mr. BOUSFIELD said that although Mr. Johnson could not speak with certainty as to the details, yet he was certain that the basis of the whole negotiation was that he was to get "controlling patents," and there came in the importance of the draft agreement. That confirmed the defendant's view, because the words therein defined the patents as being controlling patents. It was a description of what the defendant was purchasing. This was the sale of rights by description just the same as the sale of goods by description, and the description was the result of the prior negotiations. The whole basis of the thing was that the defendant was to get rights under controlling patents. He was not able to give the details of interviews upon the subject, but defendant was able to give the general result. If this licence could have given the defendant valid protection he would not be there fighting now to get rid of it.

Mr. GRAY, following Mr. Bousfield, submitted that the words "controlling patents" meant something more than a mere adjective applied to the word patents. The plaintiffs could have said that they possessed "patents," but by the qualifying word they implied that their patents could control the market, and prevent any other other double-enclosure lamp at all. Then the terms were to be the best given to any other licensee.

His LORDSHIP, after pointing out that the defendant himself had disclaimed any imputation of fraudulent intention in the representations made to him by the plaintiffs' agent, said that the counterclaim sought to set aside this licence on the ground of misrepresentation. It was said that at the time of the licence being entered into the plaintiff company did not possess controlling patents. What controlling patents there were perhaps not altogether plain; but however that might be, that was the only representation alleged, or that it had been open to the defendant to allege; and it was reasonably plain on the evidence of the defendant himself that he did not remember any other representation having been made to him. He (Mr. Justice Farwell) held, as matter of construction, that there had been no misrepresentation at all. The fact was that the defendant knew a great deal about these matters, and it appeared plain to him that what he was dealing with were patents merely described as controlling patents, meaning the Howard patents and nothing else. He understood that some one else could make enclosed lamps in this country, which showed that he held these patents to be valid patents. As to the letter asking an assurance for a licence which should be on precisely the same terms as those given to other licensees, it was only fair both to Mr. Drake and to Mr. Johnson, to say that there seemed to have been no intention on either part to deceive. Mr. Drake gave the assurance that the terms he was offering were the best that his company gave to anybody except Stewart's, who, as he informed the defendant, were the first people. The General Electric Co. could, at the end of three years, put an end to their licence, and they were freed from the condition put upon other licensees that they should not contest the validity of the patent on the termination of the licence. The defendant now complained that while he had to run the whole term of the licence, he had not a similar provision; but it was quite plain that at the time when he took that licence he was anxious to get it for as long as he could, because he thought it was a good thing. He knew as much about the matter as Mr. Drake did; and the suggestion that if he had known about that proviso in the licence to the General Electric Co. he would not have accepted the licence his lordship could not adopt. His lordship was therefore of opinion that the licence was

Digitized by Google

given on the best terms, and therefore he must dismiss the counterclaim with costs. His lordship then took further evidence on the plaintiffs' claim in the action.

Mr. DUGALD CLERK, recalled and further cross-examined by Mr. Bousfield with reference to Howard's patent, said that precautions were taken in the specification for enclosing it air-tight by means of a washer, which was nipped in with screws and other equivalents.

Mr. BOUSFIELD: Now I put it to you that, having regard to the knowledge at the time, "enclosed air-tight at all points below the arc" means closed air-tight in the manner described in this specifiation?—I think it means closed air-tight in any way.

Mr. JAMES SWINBURNE, examined by Mr. Moulton, said he had read the Howard patent. With reference to the sixth claim, the arc lamp had got its arc enclosed in a transparent or translucent envelope. It was closed air-tight at all points below the arc, and was provided with a plug at the top, having a closely-fitting feed opening for the positive carbon. In his opinion, it fulfilled the description of claim 6. In claim 12 the arc lamp had obviously got "an auxiliary transparent or translucent envelope enclosed on all sides surrounding said arc enclosing envelope." It had got feed openings in the globes and the whole arrangement gave that affect.

Therefore was made in accordance with the claim?—Yes.

His LORDSHIP: You do not ask about the other specification?

Mr. MOULTON: No, I do not rely on that.

Cross-examined by Mr. BOUSFIELD.

I put it to you that what this specification means by "closed air-tight" is such air-tightness as you would get by the insertion of a washer?—No; that is what the patentee describes; but as it is comparatively open at the top, it is obvious that what he means is really that it is closed so that there shall not be an in-and-out draught of air at the bottom, so that the communication with the outer air shall be practically all at the top. It is not necessary to close the bottom so as to stand pressure or make it contain water or anything of that sort.

I put it to you that the same interpretation of these words "closed air-tight" and "a closely fitting feed opening" which justifies you in saying that it is within their claim, would equally justify you in saying Beardlee also, which is before, is within the claim?—I do not remember Beardlee's lamp.

With regard to claim 12 WITNESS said he did not think it chokes in the sense of preventing any pressure inside the globe. The only result of that communication being along through the top of the lamp would be that you would not get much convection. If the air expanded inside, it would get out perfectly freely, but you would not have draught in-and-out.

Mr. BOUSFIELD: Do you say in your view that our envelope is, within the meaning of that claim, an envelope closed on all sides?—Yes; I think so.

Mr. MOULTON: Tell us what the object of the air-tightness at the bottom of the envelope is?—The inside of the envelope when the lamp is working is full of exceedingly hot gas and if you gave it a chance it would act like a lamp chimney, the cold air would get in at the bottom and the hot air go out at the top, but by closing it at the bottom you prevent any circulation through it.

For that purpose is the lamp of the defendant practically airtight at the bottom?—I think so; certainly.

Are you speaking of the outer globe?—No; the inner globe.

Is that for the purpose of substantially preventing air passing through?—I do not know what its purpose is, but it does prevent it, and if the grinding is not absolutely true, if you look at the lamp you will find that the top and bottom can move slightly so as to fit any untruth there may be in the grinding.

So that, aye or no, it is practically airtight?—Yes.

Now with regard to the space at the top. Kindly look at page 4 of the specification, the last words before the claims: "The narrow opening before the positive carbon, between the latter and the metallic plug or thimble permitting egress of heated gases." Does that point to a narrow opening between the carbon and what contains it?—Yes, I think he has no valve there. He wants an opening, and he either has it through a valve or has it round the sides of the carbon.

He says you may have it round the sides of the carbon, or through a valve?—Yes.

Considering that, is the space that there is round the carbon excessive, so as to be out of harmony with the description in the specification?—No, I doubt whether it is as much as is shown in Fig. 5.

And if you look at page 3, "In my lamp, however, the enclosure, although practically tight against ingress of air, allows a steady outflow of gases from the lamp." Does that accurately describe what this does?—Yes.

Mr. BOUSFIELD: But that is a reference to the action of the valve.

Mr. MOULTON: Yes; but he says at the end it is instead of the valves.

Mr. Justice FARWELL: Yes.

By Mr. MOULTON: The narrow opening had to do what the valve did, or nearly so. They both were amply sufficient to prevent any convection—that is, any gas flowing in and out at the same time.

This ended the examination of plaintiffs' witnesses, and a long legal discussion followed as to the formal proof of documents supposed to be in *de bene esse*. After which,

Mr. HERBERT JOHN MARCUS proved the execution of an agreement of March 23, 1897, between the Electric Arc Light Co. and the Jandus Arc Lamp and Electric Co.

This closed the plaintiffs' case.

Mr. BOUSFIELD said that with reference to this claim of title what they had to look at was what was the position of things on March 24, 1898, and the question was of course what controlling patents they then possessed. At the date of the licence the maker was taken entirely on trust. They were getting certain patents which were to be controlling patents. They asked the defendant to take a licence, and he did so on the assurance that he was going in with the rest of the trade, and was going to get it on the same terms. They had a remarkable form of licence, and the plaintiffs were no more entitled than they were to go outside its terms. At the date of the licence he should say that as to the Howard patent they had not got it and had not the right to get it, and on this question of title he should submit the plaintiffs had made no case.

Mr. Justice FARWELL: If you satisfy me that they had not got it either in law or equity then I should be with you.

Mr. BOUSFIELD said the agreement of March 23 recited that the vendor company claimed to have certain rights in the Howard patent. What had become of those rights?

Mr. Justice FARWELL: The legal title being in Marks, and an assignment being duly registered, that would be conclusive, would it not?

Mr. BOUSFIELD said that was *prima facie* evidence of the title, but it came after the date. They could have no further fact after the date of the licence. In this document there was a clear notice to all the world and to the parties that it was the vendor company which claimed the right to the Howard patent. Marks' agreement was a personal agreement, under seal to carry out the provisions of the agreement so far as related to matters within his control. He took it that meant that he would make a struggle to get the patent for the Electric Co.

Mr. Justice FARWELL: It meant if he got the patent he would convey it according to the agreement.

Mr. BOUSFIELD said the two points he would put were first that on the face of the document the Electric Arc Light Co. were owners of the patent, and it must be shown that their rights were discharged before a title could be shown, especially when it was an equitable title his friend was relying upon. The next point was that the title they were relying upon was a title which came through the personal agreement of Marks, which personal agreement did not appear to have anything to do with the arrangement of the patent, but appeared to be an agreement for services—a personal agreement. Then he said it was *nudum pactum*, and that it could not be enforced. Then there was a further point, and it was that, assuming that Marks and the Electric Arc Light Co. were the same persons, and assuming, therefore, that on the 19th Feb., 1898, not merely Marks but the Electric Co. had got this patent, he contended that even then there was no equitable title with the licensors. Even if the Electric Arc Light Co. had got the patent instead of Marks the Jandus Co. could not have enforced specific performance.

Mr. Justice FARWELL: It really goes to the root of the whole matter if you are right. Assume that you could not have specific performance of an agreement to do the best you can to get because it is too vague or it is personal service. Suppose he did get it. Cannot you after that get specific performance?

Mr. BOUSFIELD said that was a point for his Lordship to decide. Counsel then directed his Lordship's attention to the specification, and pointed out differences which he contended existed between the plaintiffs' and defendant's apparatus. The specification spoke of "the enclosed air and gases between the outer and inner envelope make the difference of temperature on the two sides of the arc enclosing envelope less and thus protects it." It was wanted therefore to have an enclosed space which was got by what was called a closely-fitting conical reflecting hood. Now the defendant found if he enclosed his like that he cracked the outside globe and therefore what was done was this. First of all he had not got that conical hood business and that feed opening in it, and what he had was a globe, as he was entitled, and as everybody was entitled to have, a globe to keep draughts off and he provided for the free escape of the heated air from the globe for the practical reason, not merely because he did not want to do what was done by the specification, but for the very good reason that if he did not do it it was found by experience that the top screw of the outer globe cracked off.

Mr. ADOLPH WUNDERLICH, re-called, said he was quite familiar with what had been done in reference to enclosed arc lamps. These lamps had been practically his design.

In your lamps when they are put together can the inner envelope be properly described as "closed air-tight at all points below the arc?"—No, because that is not what I consider air-tight.

Supposing the envelope was sealed air-tight without any provision of a valve, the expansion of air would tend to break the envelope?—Tend to fracture it.

Or an accumulation of gases might tend to an explosion?—Yes.

Having regard to the way in which this lamp is put together with these loose joints of glass or metal, would a valve be of any service in your lamp?—It would be entirely unnecessary.

Is it, in fact, air-tight?—No.

How is air-tightness secured in the specification?—It is secured by asbestos washers in every particular place where it is mentioned.

What is the practical result when you make a lamp practically air-tight with asbestos washers?—You do not consume any carbon whatever, and the result is you do not get the result that I care to attain.

What is the result of making them practically air-tight as regards the decomposition of carbon?—The carbon is deposited on to the negative, so that it would fly off on to the globe, which blackens rapidly and therefore you lose all transparency.

Is the admittance of air by joints in the lamp an advantage or otherwise?—A great advantage.

We have got a certain standard given us of what the Howard lamp is going to do. It tells us two things; first of all, it tells us the consumption of the carbon is so slight that the negative carbon actually gets longer instead of shorter. Is that the case in your lamp?—No. It gets much shorter.

Next it says "a carbon of less than 12in. in length will maintain the arc and its gaseous envelope in continuous operation for more than 100 hours with a consumption of 270 watts." Taking that as a standard, does

Digitized by Google

your lamp come up to anything like that as regards the consumption of carbon?—No; taking into consideration the watts that it mentions.

Supposing you packed the joints with asbestos, what difference would it make in the consumption of the carbon?—If packed tightly I should get about 100 per cent. longer life of the carbon.

Now with regard to claim 12, We are told in the specification that it was not a novelty to enclose the arc in an air-tight envelope?—No.

The term "enclosed arc lamp" means a lamp with one air-tight envelope, or more or less airtight envelope, to enclose it. Had it ever before been proposed to use a second envelope, closed at the top to keep draughts off the inner enclosing envelope?—No.

Cross-examined by Mr TERRELL: He had had experience in lamp making before he was in the employment of Mr. Johnson. Speaking as an arc lamp maker, he should say Howard wanted to describe in his specification something which was absolutely air-tight in the inner envelope, or something that was sufficiently air-tight to serve the purpose which he described.

In your lamp have you not got practical air-tightness?—Not in the sense that you speak of it as an arc enclosure.

You get actual pressure inside resisted, do you not?—Yes.

When the lamp is burning there is no vacuum inside?—No.

Therefore the pressure of air outside and the pressure of air inside are pretty nearly balanced when the arc is burning?—Yes.

Now as to the 6th claim. The lamp complained of as being within the licence is an arc lamp, with its arc enclosed in a transparent or translucent envelope?—Yes.

That is closed, but you say not absolutely air-tight at all points below the arc?—Not in the sense that is here described in the specification.

When you started devising the lamp that you are making DC, did you have the specification handed to you?—Not that I can remember, but I have had the specification.

What year did you start devising this arc lamp?—About 1898.

Did Mr. Johnson tell you to devise a lamp?—Yes. He told me he thought there was a large scope for enclosed lamps, and that there was no reason why we should not make one.

Did he tell you he had a licence under Howard's?—Not that I remember.

Did you have Howard's lamp before you when you made your lamp. I put it to you that in devising this lamp one of the objects you had in view was to try to get outside Howard's if you could?—No. I did not attach any value whatever to Howard's specification at any time.

Prof. SILVANUS P. THOMPSON (examined by Mr. Bousfield): Taking defendant's lamp, are the joints air-tight in the ordinary and common meaning of the word air-tight?—The bottom is certainly not. As to the top joint it depends which way you put the glass in. One end of the glass makes a better fit than the other.

I have asked you to answer the question with reference to the word "air-tight" in its ordinary and natural meaning. Now I will ask you as to a modification which has been suggested. Having regard to the purposes of this specification, in which you described how to make an air-tight joint, and how to provide against its keeping in too much air by the use of a valve which is to let the air out, are the joints in ours practically "air-tight," having regard to what is described in the specification as the purpose of the joints?—As I read the specification the word "air-tight" is used in two slightly different senses. It is used with reference to a joint, and it is also used with reference to a vessel. A vessel may be practically tight against ingress of air by being absolutely closed at one end and narrow at the other.

I want to refer you to the claim. The plan apparently here is to make it closed air-tight at all points below the arc, and then to have a closely-fitting feed opening above. I suppose the feed opening above, with a sliding contact with an asbestos washer, could hardly be decribed as an air-tight opening taking that point by itself?—I should not so describe it.

Taking the two points, does the lamp of defendant's conform to the method of getting an air vessel tight?—I do not think so.

Mr. JOHN IMRAY gave evidence on some points. Taking the defendant's lamp, he did not think it could be described as air-tight, using that word in its ordinary and natural sense.

Mr. GRAY summed up the plaintiffs' case. He contended that the two claims must be construed for the purposes of infringement so as not to exclude mechanical equivalents, and if that was so he submitted they were entitled to succeed.

JUDGMENT.

His LORDSHIP, in giving judgment on Monday, said: I think the defendants in this case have raised every conceivable objection that could possibly be raised. The first point made by Mr. Bousfield was on the construction of the agreement. He says that there is an interest there recited to be believed to be in the Electric Arc Light Co., and that is not got rid of. It seems to me the short answer to that is that I have here the Patent Office register. It shows that the Jandus Co. are registered as sole proprietors under an assignment from Marks, and were so registered on May 16, 1898. The second point which he takes is that that argument is *nudum pactum* because in effect the Jandus Co. took from Marks and from the Electric Arc Light Co. I can only say, so far as *nudum pactum* is concerned, I really do not follow it. Marks executes a memorandum at the end of the agreement, in which he says: "I personally agree to carry out the provisions of this agreement so far as relates to matters under my control as though I had been an original party to this agreement." That agreement contains, amongst other things, a provision that "the purchaser company will pay to the vendor company a further sum of £1,500 upon the vendor company assigning or obtaining an assignment from the purchaser company of the said Howard patent." How could that be said to be a *nudum pactum* when it is in effect an agreement by Marks in consideration of the payment at his request to the Electric Arc Light Co. to procure to be assigned the patent I fail to see. That point seems to me to come to nothing. Then there was an ingenious point suggested that this was an agreement of which you could not get specific performance, and therefore it was said if you could not get specific performance you did not get the equitable title at the date of the licence, because it is by reason of your being able to get specific performance that equity considers that as done which ought to be done, so that the equitable title passes. Mr. Bousfield pressed upon him (his Lordship) that this was really an agreement to give services, and not an agreement to assign a patent. But he could not shut his eyes to what was the true intent of clauses 2 and 3 (which Mr. Bousfield read) of the agreement, although there was this to be said in Mr. Bousfield's favour, that the parties had some inscrutable reason for not going on *in termo* to say that if and when the Electric Arc Light Co. did get that Howard patent they would assign it. But, continued his Lordship, I find these words by implication in clauses 2 and 3. The argument pressed upon me was that it would be only damages, and not specific performance. That argument in itself assumed a contract to assign, because you could not get damages for breach of a mere agreement to do the best you could, if you had actually done the best you could to get the assignment, and therefore the only matter for which damages could be recovered would be for not assigning the patent when you got it. That is to my mind the true meaning of the agreement. And if that be so, if it be the effect, as Mr. Bousfield put it, that you could only get damages, it is fatal to him, because whether the remedy be damages or specific performance the right of action is the same. That leads me to the point of substance in the case, which is a question whether the article made by the defendant infringes the invention of the plaintiffs so as to be really made within the licence. Now I have heard an argument which would have had very considerable force if it had been addressed to the validity of the patent, but that is not open to the licensee, and the whole of the struggle was to get in evidence by putting in former specifications, and the struggle to put in evidence which I have overruled, and to which Mr. Bousfield returned again and again, is entirely with a view to show that the patent was not good. Over and over again in the course of the witnesses' evidence and in the course of Mr. Bousfield's address it plain that what he was striving for was to do that. Now this is not open to him. He is bound to admit that the patent is good, and that being so I am proposing to construe this patent simply and solely by the words the parties have used contained in the four corners of the specification. What I have to consider is whether in the fair meaning of this patent the defendant's lamps are an infringement or not. On the evidence as it stands—leaving out Mr. Wunderlich's, as to whom I have already made some comments, and I do not like to say a thing of that sort twice—it seems to me that there is no dispute really. First of all it is "an arc lamp having its arc enclosed in a transparent or translucent envelope enclosed air-tight on all points below the arc." His lordship went on to say that everybody agreed there that "closed air-tight" did not mean hermetically sealed, inasmuch as he had had explained to him the object on one side of preventing a current of air arising and avoiding as far as possible contact with the carbon, and on the other side to allow some escape of the hot gases which otherwise might cause an explosion. He had got what was reasonably plain on the face of the specification, a provision by which you could not have a hermetically sealed enclosure, nor could you have one nor did you desire to have one which was open to all the winds of heaven. The invention was of something which gave a mean between the two. He was invited to say that "closed air-tight on all points" was so air-tight on all points below the arc as to necessitate the provision of a plug at the top. He did not think that was a fair construction. The recital part of the specification showed that, although the inventor dealt with arc lamps with enclosures and with valves, he also dealt with those where there may be an opening not by means of a valve. It was said, moreover, by one of the witnesses, that provided with a plug at the top would not apply to DC1. On the evidence I find it does. I disregard that particular item of evidence, and I understood Mr. Bousfield to admit it—at any rate, whether he did so or not, I think it is so. Then we had some little light thrown on the meaning of "closely fitting" by the next words: "Having a closely-fitting feed opening for deposit of carbon." It was plain to his Lordship, as Mr. Bousfield pointed out, that "closely-fitting feed," there referred back to the closely-fitting feed mentioned on p. 2, line 25, of the former specification, which was a "comparatively close-fitting." So he had words which under the rules of construction allowed him to read as "comparatively" close-fitting. All the witnesses agreed that it meant comparatively close fitting. To his mind DC1 came within claim 6, and it was said to come within claim 12. He did not propose to go through the evidence in detail. It would be convenient to refer to it in another place if necessary, but he should like to point out that Prof. Thompson agreed with his lordship's views. It seemed to his lordship to be a plain case of infringement, and therefore there must be the order as asked.

Mr. MOULTON: There will be judgment for the plaintiff on the claim for the account and for payment of the royalties?

His LORDSHIP: Yes.

Mr. GRAY: I do not think the form of your account is quite right when it says you seek an account of all lamps made under the licence.

Mr. MOULTON: Made or sold.

His LORDSHIP: The Registrar points out to me that that is not the common form, "all lamps made or sold."

Mr. GRAY: Then, my, lord, they sued us on two patents and they have only proved infringement of one.

His LORDSHIP: I do not think that has made any difference as to costs. I am not favourably impressed with the honesty of your defence. I am not disposed to give you any favour at all. I see no reason for making any difference.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON,

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "The Electrician" *commence in April and October.*

"The Electrician" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II:—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof J. A. Ewing, M.A. New edition. Price 10s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. Curtis-Hayward, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. Raphael. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By Dane Sinclair and F. C. Raphael.

SPECIAL NOTICE.

NOW READY.—Vol. XLIV. of "The Electrician" (950 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "The Electrician" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

THE TYNESIDE ELECTRIC POWER BILLS.

During the past week the Select Committee of the House of Commons, presided over by Sir James Kitson, has heard the evidence in favour of and against two electric power bills, which are included in the category of six important bills discussed in general terms in our leading article last week. It seems probable that by the time this issue is in the hands of our readers the Committee will have progressed no further with its laborious task than to have heard the opening of the case for the third bill on the list—viz., the Lancashire Electric Power Bill, a map of the area relating to which will be found on another page this week. At this painstaking but tardy rate, the Committee will probably require to sit throughout another entire week or more before arriving at the conclusion of its work. This strong Committee, however, is doing its work so carefully and well that all who are interested in the progress of electrical power industry may patiently await the final issue with good ground for hoping that the claims of the electric power schemes will receive just consideration and treatment at its hands.

The two schemes which have occupied the attention of the Committee are: the County of Durham Electric Power Supply Co.'s scheme, and the Tyneside Electric Power Co.'s scheme. The hearing of the former occupied from Friday last until Monday evening, and the evidence for the Tyneside scheme was commenced on Tuesday morning. These two schemes, as is made clear by reference to our maps, are to some extent competitive, inasmuch as each includes within its area the districts on the south bank of the Tyne. So far as the Durham scheme is concerned, this region has been the principal centre of opposition—partly on account of the competitive scheme of the Tyneside Co., but also because of the remarkable hostility of two petty local authorities at Hebburn and Felling, about which we say more further on. But the Tyneside Co.'s scheme met with far more formidable opposition, not only from the rival Durham Co. and a large number of local authorities within its proposed area, but also from the Newcastle-upon-Tyne Electric Supply Co., who are owners of large electricity works doing a considerable electric lighting business with single-phase alternating currents.

It would be superfluous here to review the entire evidence presented in connection with these two schemes, for our readers will find a *resumé* of the evidence in the columns of

Digitized by Google

our "Parliamentary Intelligence." We shall devote the remainder of our space in this article to consideration of one or two salient points. In the first place we wish to traverse the view which has been advanced that these schemes are unjust because they will pick out the plums from among the consumers and leave the local authorities the task of supplying all the less profitable consumers. It is alleged that to allow this would be to raise the price at which the small consumer for lighting purposes would have current offered to him, because it is the big consumer who helps most to pay for running the electricity works. If this is held to be a grievance of the small consumer, is not the converse an even greater grievance on the side of the man who is anxious to take power wholesale for the purpose, say, of manufacturing goods cheaply? The power companies offer him electricity at a low price; but the local authority steps in and declares that this low price is an injustice, for the manufacturer, it asserts, ought to be saddled with a portion of the cost of supplying electric light to all and sundry. The injustice of the contention is palpable. We ask, are schemes which are being fostered mainly for the encouragement of power-consuming industries to be defeated because they are framed in such a way that power for such purposes will be supplied at a much cheaper rate than a local authority could supply it from its lighting works? Moreover, it must be borne in mind that this outcry about the grievance of the small consumer is only a myth; for, inasmuch as the power companies can always supply current wholesale to a local authority as cheaply as, or even cheaper than, the local authority could generate the current for itself, it will be easy for the local authority to provide for the small consumer just as cheaply as it would be able to do if it had its own electricity works. If it is said that the presence of the power supply company in any area would prevent the local authority from erecting its own works, because it could not secure the manufacturers as consumers, the obvious answer is that such a local authority would not require to erect its own works; the conditions obtaining would unmistakably indicate that it could obtain its current more cheaply by buying it wholesale.

This brings us to the attitude adopted by the petty districts of Hebburn and Felling towards the two Tyneside power schemes, an attitude which directly illustrates the foregoing remarks. Hebburn and Felling do not want to be included in either of these schemes. Both by learned counsel, and by the less learned but not less authoritative voice of the chairman of the Felling Urban District Council, they have emphatically declared this to be their position. Not even if electric power were to be offered cheaper than they could possibly generate it themselves under the most favourable conditions would they move one inch from that position. They mean to keep the electricity business in their own hands: if there is any profit in it for a company they are convinced—such is their simple-minded credulity—there must be a profit in it for themselves. This is the typical attitude of the petty local authority; we may therefore examine further the action of these two District Councils. We have before us copies of the reports of the consulting engineers engaged by these councils. In our leading article last week we expressed a hope that no member of the electrical profession might be found who would be willing to contest the principle of these power bills. But the occasion, apparently, has produced the man—or, rather, the men—in the firm of Messrs. Handcock and Dykes, of Westminster. The reports presented by these gentlemen are calculated, in our opinion, to give a most misleading impression as to what these two Urban District Councils could accomplish for themselves in electricity supply. Alas, we suspect that their clients were all too willing to be led into the false belief that they could accomplish it. Thus have the blind led the blind. For brevity sake, we shall confine ourselves to the Felling report; that to the Hebburn Council is its twin brother. The population of Felling is but 22,000, and the district boasts of 405 street lamps. It is proposed to erect a power station of 500 kw. capacity, and to equip it with plant of 110 kw. capacity—with all necessary mains for street lighting with glow lamps and 1,500 private lamps—for a total capital outlay of £15,510. This modest expenditure is to provide for an annual output of 162,000 units sold—an astonishing feat, to be accomplished, it appears, by the really delightful estimated load-factor of 25 per cent., and a maximum demand of only 70 kw. Where can these sanguine consulting engineers point to any station of the same small size, and doing the same class of business, which has so large an output or so small a maximum demand? We have searched in vain, not for an example, for that would be waste of time, but for anything approaching these results. The nearest example we can find is Dewsbury, where an output of 161,154 units last year involved a maximum demand of 190 kw., the capital expended on the works being over £26,500. Taunton furnishes another instance, the output, maximum demand and capital expended being 171,083 units, 220 kw., and £28,800 respectively. Ayr, Richmond and Whitehaven also furnish examples of works with approximately the same output as is estimated for Felling, but with enormously greater capital outlay. To proceed with the report. On this modest outlay of about £15,000 there is to be an annual gross revenue of £2,150, made up of items, £1,053 for street lighting, £972 for private lighting, £100 only for power consumers, and £25 for meters. It will be seen that practically all the business is to be electric lighting, and the bulk of that is the street lighting, which the District Council will do on its own behalf. The tariff is to be 5d. for the first 100 hours, 2d. for the second 100, and 1½d. for subsequent consumption; so that on this tariff it is expected to derive from this little undertaking a gross revenue of no less than about 14 per cent., or £22 per kilowatt erected at the works—more than twice as much as is realised with existing works of the same output as that estimated. And these eminently satisfactory results are obtained—on paper—with an annual expenditure of only £1,220, which, be it observed, is at the rate of only 1·8d. per unit sold. We invite the attention of the District Council of Felling to the following particulars of what electricity has cost at works of the size it proposes to erect. At Guildford, with 3,000 lamps connected and a station capacity of 120 kw., the costs were 5·8d. per unit; at Harrogate, with 15,800 lamps and an output of 201,364 units, the costs were 3·34d. per unit; at Taunton, under similar conditions, they were nearly the same figure; at Whitehaven, with 8,267 lamps connected and an output of 206,364 units, the costs were over 2d. per unit. Instances might be multiplied, but the foregoing should suffice to prove that the estimated expenditures and results for the proposed municipal works at Felling find no justification in the corresponding figures for actual practice on any comparable scale. Indeed, we go further: we assert that these estimated figures are entirely misleading, and insofar as they have led the District Council of Felling into persisting in its hostility to the power bills, the authors of them are to be severely condemned. At the present juncture, reports of this description cannot be held up to too emphatic scorn. Like an election dodge, their purpose in defeating the opposing schemes may be accomplished long ere the hollowness of their pretensions

Digitized by Google

can be realised. Our advice to Felling and Hebburn is to retract before it is too late; they may be sure they will never be able to run their own electricity works on the lines of these reports. And if these little local authorities persist in their obstinate opposition, we trust the Select Committee will refuse to remove them from the areas of the Tyneside schemes. Little local authorities who do not know what is best for themselves should be made to know by Parliament.

A CENTURY OF CHEMISTRY AT THE ROYAL INSTITUTION.

(*Continued from page 57.*)

LECTURE II.

The second lecture of this course was delivered by Prof. DEWAR, F.R.S., on Thursday, May 3rd, at the Royal Institution. The lecturer began by defining some of the terms introduced by Faraday, in connection with the phenomena of electrolysis. A question which considerably agitated the minds of physicists and chemists during the first half of the present century, was the condition of the solution in the space between the electrodes and in the line of the current. Faraday tried repeatedly, but always failed to discover any effects.

Davy was the first to propose a theory of electrolysis which sought to explain the phenomena by the repulsion of similar charges on the corresponding parts of the molecule. The neutral behaviour of the intermediate liquid was thus ascribed to the superposition of equal and opposite charges. This is practically the same theory as that which Grotthus further developed in 1805. According to Grotthus' theory, every molecule consists of a positively and negatively charged portion; the molecule nearest the positive electrode is decomposed and the negative portion attracted, the remaining portion passing on to the next molecule, decomposing it and replacing the positive portion. And so on, through the solution, the effect is transmitted in much the same way that an impulse is transmitted along a series of elastic balls. Grotthus' theory had to be subsequently rejected because of its utter inability to explain the difference in concentration produced in the electrolyte in the neighbourhood of either electrode. This could only be explained by the "migration" theory, now generally accepted as true.

After some remarks on the changes which the form of chemical equations have undergone in recent years, in consequence of the ionic theory of chemical action, Prof. Dewar showed a number of experiments to prove that the pile was electrically active only when the conditions permitted of chemical activity. Thus, a pile immersed in alcohol at ordinary temperatures, will produce a considerable deflection on a galvanometer; if, however, the alcohol be cooled to near its freezing point by the aid of liquid air, so as to render it chemically inert, no deflection whatever can be observed.

On Oct. 19, 1807, Davy succeeded in decomposing potash, thus performing one of the most important experiments in modern chemistry, proving the possibility of the compound nature of every substance believed to be elementary. Lavoisier and others had conceived the possibility of the compound nature of the alkalies, but the use of electricity to prove this was first appreciated by Davy. After some similar experiments proving the elementary nature of phosphorus, sulphur, and other substances, in which he did not allow himself to be carried away by appearances, he carried out his brilliant research on chlorine. Berzelius and Scheele both believed this to contain oxygen, but Davy satisfactorily disproved this hypothesis. Again, on the discovery of iodine, Davy immediately suggested its relation to chlorine, and showed the similarity in behaviour of hydriodic and hydrochloric acids. The lecture concluded with an account of the investigations leading up to the final form of Davy's safety lamp for use in mines.

(*To be continued.*)

CORRESPONDENCE.

MATTHIESSEN'S STANDARD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As Dr. Everett has clearly shown, the "Committee on Copper Conductors" have only added to the confusion at present existing with regard to Matthiessen's standard. It seems to me that, before a new value of an *arbitrary* standard is adopted, it should fulfil the following conditions. It should be (*a*) Simple; (*b*) Clear; (*c*) Universal; (*d*) Easily remembered.

Now, the proposed standard fulfils none of these conditions.

(*a*) It is not simple, since it requires for its description such numbers as 0·150822 and 0·153858!

(*b*) It is ambiguous, since it has two values where one is amply sufficient. The retention of both a hard and a soft standard is both unnecessary and confusing; the ambiguity might even lead to fraud.

(*c*) The proposed standard, in its present form, cannot be accepted by the nations who use rational weights and measures, for it is based on the Fahrenheit scale. (The standard density suggested is practically incommensurable in scientific units.)

(*d*) The definition of the new standard is not easily remembered.

In contrast with all this I may mention the value of the copper standard which I have used for some years—viz., "0·1500 international ohms at 15°C. for 1 metre 1 gramme." This is *simple*, *clear*, *universal*, and *easy to remember*; besides it agrees closely with the value given by Matthiessen for soft copper, though one can hardly admit that this agreement is of any real advantage.

ALBERT CAMPBELL.

London, May 8.

NATIONAL TELEPHONE CO.'S ANNUAL STAFF DINNER.

The seventh annual staff dinner of the National Telephone Co. was held at the Trocadero Restaurant, London, on Friday last, Mr. WM. E. L. GAINE, the general manager, presiding. The company present numbered about 200, and included Lord Kelvin, Sir Albert Rollit, M.P., Sir Cuthbert Quilter, Bart, M P., Lieutenant-Col. C. B. Clay, Prof. Silvanus P. Thompson, F.R.S. (President of the Institution of Electrical Engineers), and a large number of gentlemen well known in electrical circles.

The toasts of "The Queen" and "The Navy, Army, and Reserve Forces," having been proposed by the chairman, and Sir Cuthbert Quilter, M.P., respectively, and very cordially responded to,

The CHAIRMAN (having first read letters from Mr. J. Staats Forbes, regretting his inability to be present on account of his state of health, and from Lord Harris owing to his being embodied in the Yeomanry) proposed the toast of "The National Telephone Co." He said: I find this is the seventh year in which I have had the privilege to propose this toast. Seven years ago the company was somewhat smaller, somewhat less important, than it is to-day. We then wished health and success to it, and, so far as we can see, health and success has followed our wishes. We have now 968 exchanges working throughout the United Kingdom, and we have been engaged, as you know, not only during the past year, but for several years past, in remodelling our system without regard to cost, except on grounds of reasonable economy, in order to bring it in every respect entirely up to date, so that it may be second to none throughout the world. I am glad to say that great progress has been made in this direction during the past year, and out of our 968 exchanges no less than 840 would compare with any exchanges in any part of the world. We are accustomed to a great deal of abuse as having the most inefficient and the most inadequate system to be found, but still the year 1899 was a record year in the history of the company. We added to our list of subscribers no less than 21,000 people, after allowing for those who, from one cause or another, had occasion to leave us—we had, I say, 21,000 net, so to speak, added to our *clientèle*, so that now we have upwards of 176,000 subscribers. This number of subscribers to the telephone is equal to one in every 214 of the entire population of the United Kingdom, and that compares most favourably with almost any country in the world—it is certainly better than in the great countries of Europe. The figures I have now to give you are interesting. My millions are greater in number than those of the Chancellor of the Exchequer. How many messages pass over these wires of ours? Last year we passed 617,000,000 messages between people in the United Kingdom, and I think some measure

Digitized by Google

of comparison may be found in this, that Her Majesty's Government passed over their wires, in the same period, 87,000,000 only of telegrams, including foreign telegrams. Now, one of the great charges made against the National Telephone Co. by what my friend Mr. Clay calls the uninformed—and I quite agree with him in that term—is as to price. The messages passed over our wires have been sent at an average cost of ½d. each, whereas Her Majesty's Government has required for each of theirs 7½d. These figures show that the most inadequate, the most inefficient service in this country—as we are told it is—is nearly seven times in volume the service conducted by the State, and is certainly infinitely cheaper. There is one other subject I should like to say a few words upon, and that is with regard to the manner in which the Post Office is conducting the trunk service of the country. Do I put it too high gentlemen, when I say that it is an inadequate service? I have, week by week, brought to me reports of all the district managers and superintendents with regard to the trunk delays which are taking place throughout the United Kingdom, and I say, without hesitation, that a very grave indictment can be framed against the Post Office for the manner in which the trunk service in this country is being carried out. I should be sorry to convey the impression that I am aiming my remarks at the *personnel* of the Post Office. It is not for me to say where the fault lies. The Post Office is a great department of the State, but behind the Post Office is another great department called the Treasury. Whether it is the fault of the Treasury in not finding the money, or the fault of the Post Office as a department, I do not know, but I am satisfied of this, that the *personnel* of the Post Office who are charged with the carrying on of this service are the men who, before all others, are dissatisfied with things as they are at present, and so it is not them whom I am aiming at in the few remarks I have made on this matter. I find that throughout the United Kingdom delays are daily experienced of from half-an-hour to two hours in duration, and I say this, that no trunk service is worthy of the name which requires a man to wait, upon an average, more than five minutes in order to have his message put through. Of course we must bow to the wisdom of Parliament, and I find that Parliament last year voted a sum of two millions of money to enable the Post Office to compete with its poor, unfortunate licencee in London. I cannot help thinking, and this is my individual opinion only, that if that two millions, and two millions in addition, had been voted by Parliament to enable the Post Office to properly conduct the service which it has undertaken it would have been very much better. I will not weary you longer. The toast I have to propose is that of "The National Telephone Co."—the health of the company. I cannot see much sign of either mental or bodily decay. I ask you to drink to the continued health and strength of the National Telephone Co., and with the toast I have to couple the name of Sir Albert Rollit, M.P.

The toast having been enthusiastically received,

Sir ALBERT ROLLIT, M.P., said: Mr. Gaine, my lord and gentlemen, I feel it a very high honour to be called upon to respond for the company. I regret the absence of our chairman under these circumstances. His silvery voice, his great eloquence, his wisdom in counsel, his strength in execution, all recall to my mind what is also suggested by the Greek name of the telephone, the many counselled Euphines, and I think the company owes to him a very great debt for that personal magnetism which he infuses into every gathering at which he is present. I also regret to-night that what my friend the chairman has referred to as the embodied "vice" of the company is absent, and has to be replaced by the personification of virtue in myself. Truly, gentlemen, no one takes more interest in the company than I do. It is the one resource left to me for, at times, a little of that scientific thought which I at one period studied at a distance under Lord Kelvin. I have played with electricity—it was the plaything of my boyhood—I have seen it just during my life become, instead of something which men fear, that which they have made their slave. The lightnings now do our errand and our bidding; they light our houses and are a source of power and energy for us in this world below; they are a great source of traction, and some people say that in the telephone they are driven to distraction. I think that those who are assembled here, and who are daily brought into contact with this marvellous instrument, should appreciate to the fullest extent the scientific character of the calling in which they are engaged, and when I see such men as Professor Thompson here I cannot but express the hope that there are many who avail themselves of his high teaching in London, and are induced to take a deep and great interest in science. Another absence that I note here to-night is one I deeply regret. At our previous gatherings we have always had Prof. Hughes, and when we speak of science we shall never forget, I think, that it was probably he who, through the microphone, made the telephone a commercial and practical possibility. It requires some courage nowadays to respond for any company. Lord Coke said they had neither bodies to be kicked nor souls to be saved. I am bound to say that the National Telephone Co. is, in this respect, no exception to the rule of the learned Lord Coke, inasmuch as we get, not only kicks and no halfpence at all, but not a *quid* for our many *pro quos*. The directors and officials of the company desire to consult, and it is our interest and duty to consult in every way the public convenience. It is for this reason we seek those underground privileges which are so constantly combatted by what I may call underground methods, and I would venture to suggest that now, under recent arrangements, we are more or less married to the State, through its trunk lines, that the more wiry twins we have as the result of that marriage the better it will be for everybody. I have spoken of the company and of the personality of the directors, but what, after all, is a company? It is a mere legal entity, a sort of incorporated impersonality. I should like to transfer from this incorporeal hereditament the thanks you have given to us to those who have done so much for the company—I mean the staff, the loyalty and ability and energy and hard work of which have enabled you to propose the health of the company with the certainty that that health will be maintained. The directors do some things, and they do them to the best of their ability. Here is my friend, the chairman, our general manager. I often think what the legal profession has lost in him and what the Telephone Co. has gained. I desire to acknowledge the great obligation under which the directors rest to Mr. Gaine. He is a man of breadth of view, of ability, and with determination in execution. Then, there is my friend, our secretary, Mr. Anns. Why, gentlemen, when we require figures to prove anything we always put the matter into the hands of Mr. Anns. Then, in Mr. Sinclair we have a most distinguished scientist—and, again, a gentleman who deserves from the directors the most public acknowledgment of the ability with which he serves the company. I might mention many more—Mr. Goddard, with whom I am frequently brought into contact, and those who have charge of the districts, and others; but I prefer to end by a general formula and say that when you drink the health of the company you drink in reality the health of the men who make the machinery of the company to go as excellently as it does go.

Mr. J. CHAMBERS, in proposing the toast of "Our Guests," said: Sir Albert Rollitt has reminded us that we miss to-night the face of one who, I believe, has been with us on all previous occasions at these our annual gatherings. The late Prof. Hughes devoted his life to science, and his memory will be kept green for a long time to come by electrical students. We have been always particularly fortunate in having the honour of the company of able and distinguished guests each year, and this year are by no means behindhand in that respect. We have with us men who have assisted and given of their best, not only for the development of electrical knowledge, but in many other directions for the good of mankind. We have with us Lord Kelvin, and I feel sure his lordship will not take it as a liberty if I refer to him as an old and greatly respected friend. He has been a friend to all electrical students, and to many others, but those of the National Telephone Co., who have had the privilege of personal communication with him, know how he has been always ready, in a kind, way, to give advice when asked. We have also Prof. Thompson with us. To him we are greatly indebted, and we are constantly referring to him, not personally, but we find him on our bookshelves, and when certain problems perplex us we go to him for their solution. We have other gentlemen with us who have done their share for the general good. I ask you to drink the health of "Our Guests," coupled with the names of Lord Kelvin and Prof. Silvanus P. Thompson.

The toast having been drunk with great heartiness,

LORD KELVIN, who was warmly received, said: I feel it a great privilege and honour to be allowed to speak for the guests of the National Telephone Co. I feel it a large responsibility to express the thanks of all the guests present for all that they owe to our entertainers, but this burden to me is lightened by my friend and colleague, Professor Thompson, being associated with me in bearing it, and it allows me to feel that we may go beyond the guests of the National Telephone Co. of this evening and thank the company for the still larger number of, I cannot say guests exactly, but grateful clients—clients who have daily experienced all the benefits that the National Telephone Co. confers upon Great Britain and Ireland. We have had some most interesting speeches to-night. We have even had a graceful and kindly tribute to the patience of the clients of the company from one speaker when he alluded to them as being sometimes driven to distraction. I must say that that is an experience not unknown to the users of the telephone, not merely in these islands, but throughout the civilised world, and a large part of the savage world, wherever the telephone is known. But who is to blame? If people would only make arrangements that somebody was at the telephone when called the complaints against the service would in ninety-nine cases out of a hundred be annulled. I read, to my astonishment, yesterday, in a report of a discussion in the House of Commons a statement that the National Telephone service in Glasgow was very bad. I think it was stated that the service there was worse than anywhere else in these islands. A more splendid tribute to the work of the Telephone Company could scarcely be paid, because, as a matter of fact, it is a very good service indeed in Glasgow, and I challenge anyone to say that the distractions which have been referred to, in more than an exceedingly small proportion of the cases, depend on anything but the unbusiness-like arrangements of the persons using the telephone. In Glasgow they are not more unbusiness-like or less prudent and sensible than people in other parts of the world. I have experienced the same thing in Philadelphia and, more or less, in many parts of the United States; and I have heard a good many people who have experience of the telephone in Norway, Sweden, Denmark, and in France and Germany, say just the same thing—that the telephone service is very good, but that the people who use it do not understand that they must know whether or not they have somebody or other at the other end, and if any delay, what the cause of it is. Twin wires will give great assistance, chiefly by helping you to hear the person you want to hear and not anybody else. In that respect the twin wire will be of very great value, and I think the same indication of the prosperity of a great organisation—biological organism—that it is very prolific in twins is sometimes an indication of good health in material prosperity and well-being. This company is at present very prolific in twins, and it is going to produce a vast number more within the next year. It is not only in Glasgow, with the, shall I say friendly, co-operation of the excellent Town Council, and in London, with the beneficent and sympathetic co-operation of the Post Office, that I believe there is a great and rising future for the Telephone Company. It will increase more and more with, and perhaps because of, threatened opposition. I do not like to be too optimistic, and certainly I cannot feel quite convinced that all the agitation for opposition is wholly in the public interest, and wholly in a spirit of friendliness to the company in the service of the public. I believe there is a certain leaven of the ugly side of human nature in what has been going on. I do not say that it is mere jealousy and dislike, and rivalry of an unkind nature that gives all the kicks which have been referred to. Sir Albert Rollit has said that the company gets

Digitized by Google

more kicks than halfpence. If so, it must get 617,000,000 kicks per annum. The kicks are mere pin-pricks, and I believe the National Telephone Co. will emerge triumphantly from all the opposition, and that, if there should be a Parliamentary discussion on the same question 10 years hence, the company will be spoken of with admiration and respect even more than it is at present. And now I must do my duty by thanking you most warmly for the delightful evening we have had.

Prof. SILVANUS P. THOMPSON who was also loudly cheered, said: Lord Kelvin has already responded for the guests who have shared your hospitable board this evening and, therefore, I am relieved from making anything like a long speech. I presume that my having received an invitation to this dinner is due to the circumstance that I have the honour this year of holding the presidency of the Institution of Electrical Engineers. Therefore, in that representative character, I should like to say how glad I am to have been here and to have met face to face so many of our members in the great electrical profession. I am informed that the number of the company's staff is somewhere between 10,000 and 11,000 persons. That is a very large number, a very considerable fraction of the whole electrical industry of this country, and it adds to the estimation in which the electrical industry is held by the people at large to find that the telephone section of it has grown to such a large proportion. We have heard a note or two to-night of a suggestion that there are some things which are better managed by the company than by a department of the State, and, for my own part, it seems to me that, at the present time, that remark might be very well thought of in some other branches of the electrical profession than by yourselves. We are now in some danger of seeing private enterprise swamped by the ambitions, shall I say, of municipal authorities, local authorities, and of the departments of State themselves. Well, I should be the last man in the world to suggest that municipalities had no rights, that the municipalities were not perfectly in their proper place in desiring to be prosperous and self-governing, and in desiring to be, to a large extent, locally independent, but I maintain that there is room for private enterprise, and we should be careful in so progressive a thing as the electrical industry that we do not strangle or maim the chances of progress by too early putting enterprises under the wing of what we may call administrative bodies. Perhaps the threatenings which have been heard from time to time in the last few years with regard to the telephone service have not been without their influence upon the National Telephone Co. They have been, perhaps, a warning that things must be kept up to date, that matters must not be allowed to drift, and that the progress we see made in other countries must be equalled, if not surpassed in our own country; and surely that is so, for if the progress, the development, the perfection of instruments, the introduction of new improvements and new inventions were to be stultified by the maladministration of a company, then that company might just as well hand itself over and become a pure piece of Governmental administration. But so long as you have your individual capacity, and exist as an industrial enterprise, not fettered by red tape, it behoves you to be alive to the possibility of improvement. In the 10,000 or 11,000 members of your staff are not there many, possibly, possessed of original ideas, men who can say what is wanted and suggest how to do it? Is not a company more likely to take up improvements and push them forward than an administrative department of the Government? I venture to believe that the telephone industry can be improved by new inventions. Here we are only about 21 years old as a branch of the electrical industry. Here is this century closing and the telephone industry developed to the extraordinary extent that we see to-day, and that in 21 years. I trust to live and be present at the next 21st occasion of the company's staff dinner. If that be so, what may we not then expect to see? Among them many things yet to be attained. Wide is the field for invention. We have yet to realise the dream of speaking across the Atlantic—above the Atlantic or under the Atlantic—to America. When I think of all that has been done and may be done by the wise administration of a company like this to foster progress—the members of the electrical profession in all parts of the world are trying to do someting to surpass us, they are trying to make electrical inventions subserve national uses—when I think of all these things, surely I am entitled to hope that some of the future improvements and inventions will come from inside the National Telephone Co. I am glad to be here and to have the opportunity of saying this to you, and I am glad to encourage you in the good progress which has been made during the past few years. Some people are, perhaps, a little afraid of new inventions. For my own part, I am glad to be young enough to rejoice in the chances of seeing something futher in the way of inventions and discoveries.

Mr. T. A. PROUT, in feeling terms, proposed a toast not in the programme, "Our Chairman, the General Manager," whose fairness and kindness had endeared himself to all the staff, whose universal wish it was that he might be long blessed with the best of health to preside, not only over the business of the company, but at their festive gatherings.

The toast was enthusiastically responded to.

The CHAIRMAN, in responding, said: I am very proud, as I have said before, to be at the head of a staff such as the National Telephone Co. possesses. I believe it to be second to none, as I do not think that any great organisation, any company, possesses a better staff than does this company. I believe it is a loyal staff; and in the times that are, perhaps, before us, loyalty will be worth a great deal to the company.

This terminated a very pleasant evening's proceedings, and the large company shortly afterwards separated.

The Prussian Academy of Science.—Among the items included in the Prussian Budget is a sum of 7,800,000 marks, for the purchase of lands in Berlin, on which is to be erected a building for the Academy of Sciences and the Royal Library.

PHYSICAL SOCIETY.

An ordinary meeting was held, by the invitation of Sir Norman Lockyer, F.R.S., in the Solar Physics Observatory, South Kensington, on Friday, April 27th, Mr. T. H. Blakesley, Vice-President, in the chair.

Sir NORMAN LOCKYER gave

"A Short Account of the Physical Problems now being Investigated at the Solar Physics Observatory, and their Astronomical Application."

The chief work carried on at the observatory is the comparison of stellar spectra with spectra obtained from lights emitted by laboratory sources. The light from a star (or the sun) and from an arc (or a spark) are focussed alternately upon the slit of a spectroscope, and the two spectra are photographed side by side upon the same plate. The number of lines in the arc spectrum depends upon which part of the arc is focussed on the slit. The image of the centre is rich in lines; the image of the edge gives a few single lines. Changes in spectra are also dealt with. The thickening and thinning of lines depends upon several things. In the first place, it depends upon the density of the substance, and thus the hydrogen lines in the spectrum of Sirius are much broader than those in α Cygni, the hydrogen being denser in the former star. Changes may also be produced by variations in quantity. A $\hat{c}$ reduction in the quantity of a substance generally simplifies its spectrum, the longest line disappearing last. The motion of a luminous body to or from the spectroscope alters the wave length of the light emitted, and produces a shift in the lines of the spectrum. The amount of deviation is a measure of the velocity of approach. In the case of Nova Aurigæ we have dark and bright lines of the same substance side by side. This shows that there are two bodies involved moving with different velocities, the one giving a radiation and the other an absorption spectrum. Another change in the lines depends upon temperature. In general, an increase in temperature produces a greater number of lines, a notable exception being sodium, which gives its full number of lines at the temperature of an ordinary Bunsen flame. The spectra of metals obtained from the arc and by sparking are often quite different. Those lines, which make their appearance or are intensified in passing from the arc to the higher temperature of the spark, are known as enhanced lines. The comparison of stellar spectra with laboratory spectra is often easy. For instance, the presence of iron in the sun and hydrogen in Sirius is easily seen. Several lines in the spectrum of Bellatrix have been shown to be due to helium, the position of the lines being exactly the same as those due to the gases from clevite. In many cases it is possible to build up the spectrum of a star from the spectra of its constituents taken at the proper temperature. For instance, the spectrum of γ Orionis can be closely imitated by means of oxygen, nitrogen, and carbon together with the well-marked lines of hydrogen and helium. We can roughly estimate by the character of the spectra of stars, the temperature of those stars, and thus arrive at a stellar thermometry. Starting with a hot star like Bellatrix and passing through β Persei, γ Lyrae, Sirius, Castor, Procyon to Arcturus, a cold star, we have a gradual change in the character of the lines which appear in the spectrum of any constituent. The widening of the lines in the case of spectra of sun spots enables us to trace changes in temperature of the sun, and we can compare these temperature changes with a variety of terrestrial phenomena such as variation in latitude. The extraordinary number of lines exhibited by many metals suggests that, what we are accustomed to call chemical elements are really complex bodies which are made up of simpler ones. Attempts have been made to build up the spectra of metals by superimposing simple sets of lines upon one another. In many cases a great number of series would be required to represent things completely. In the case of hydrogen it would be necessary to have at least 27 series to give the structure spectrum only. Taking the atomic weight of hydrogen as unity, the atomic weight of the little masses which might give use to any one of the series would be about 0·0019. This is of the order of magnitude of the small bodies whose existence has been suggested by Prof. J. J. Thomson from his work on ions.

LEGAL INTELLIGENCE.

(*Continued from page 93*).

Chamberlain and Hookham v. the Corporation of Bradford.

In the Chancery Division of the High Courts of Justice, on Tuesday, Mr Justice Farwell commenced the hearing of the action by which the plaintiffs, Messrs. Chamberlain and Hookham, seek to restrain the Mayor and Corporation of Bradford from infringing a patent for electric light meters held by Mr. Hookham, and numbered 4,225, of 1885. Mr. Moulton, Q.C., Mr. A. J. Walter, and Mr. Gray represented the plaintiffs; and Mr. Cripps, Q.C., Mr. Bousfield, Q.C., and Mr. Graham represented the defendant Corporation.

Mr. MOULTON, in opening the case, said that the action was brought by the plaintiffs on letters patent No. 4,225,* of 1885 (twice amended), which were granted to Mr. George Hookham,† and the defendants were the Mayor and Corporation of Bradford. The patent was for an electric meter —that was to say, an instrument which registered the amount of electric energy supplied on an electric lighting circuit to a house or to any other establishment. This patent had stood the test already of an action before Mr. Justice Wills,‡ who supported, and all the defences, conceivable and unconceivable, were raised in the present case, including some which were decided by Mr. Justice Wills. He did not propose, in his opening, to deal particularly with those defences because he had the certificate of validity already, and he did not know on what particular portions of the defence his learned friends would rely. Many of the points raised were points of law, and on these this court would follow the decision of a court of co-ordinate jurisdiction. The essence of a useful system of supply was that it should be kept at a uniform pressure, and well-managed companies kept their supply within one or two per cent. of the proper pressure. What he had to deal with was the measured quantity. "Quantity of electricity" was an idea which, although necessary for theoretical purposes, was most unhandy for practical life, and so they reckoned total quantity of electricity by the current running for an hour, and thereby took the standard of current. They reckoned it by ampere-hours—that was to say, the amount which one ampere would carry along in a whole hour. So far he had been dealing only with the current, and current told them very little about the amount of supply. Now, the Board of Trade unit was one of 1,000 amperes at 1 volt pressure. If the standard pressure at which all these systems were worked was 100 volts, the Board of Trade unit corresponded to 10 ampere-hours at that pressure. They therefore had to measure the quantity supplied in ampere-hours. If they had that they had an accurate measure of the energy that was passed in. Edison's electrolytic meter worked very fairly, but only as a pioneer idea. There therefore remained a hopeful field for designing a proper meter. The learned counsel then explained to the Court a rough model of a dynamo. When the brushes were connected to a source of electric current the armature tended to turn round, and the strength with which it tended to turn round depended clearly on the magnitude of the current which went into the armature. If they kept the outside magnet quite constant, and measured the twist to see how much it was attracted then they could get an indication of the current at the moment. The next step taken was for measuring the amount supplied over a long period. The twist was proportional to the current, and it was necessary to balance this twist by making the armature of the motor, in turning, do work against a resistance which increased with the speed of the meter until it balanced the twist. Some people had employed paddles in a liquid for this resistance or brake, but true proportionality to the current was not attained by this means. This could be done by a copper disc rotating between the poles of a magnet, and such a brake was explained to the Court with the assistance of a model. Mr. Hookham was the first person who used the principles in the combination now before the Court in such a manner as to make a practical meter, and that was practically the judgment of Mr. Justice Wills. He (Mr. Moulton) had pleaded on this subject before Mr. Justice Wills with some earnestness because when he had his first installation at his own house he had found that his first account was 95 per cent. wrong. But, to proceed, the meter ought to start very willingly and with little force, otherwise there would be a supply which would not be recorded, and therefore it would not be accurate. The meter must also rapidly take up its steady rate. There must be little mechanical friction of the pivots because that would blur the accuracy of the registration. Mr. Hookham early recognised that what they had to do was to increase, as far as possible, the supremacy of electrical forces and diminish, as far as possible, the interfering forces. He was the first to discover how to produce a practical meter of this kind, and the success of it had been very great indeed. His lordship had before him the meter exactly as it had been drawn in the specification. The principle was still the same. Any changes were changes of detail or of greater perfection of workmanship, and the meters had won for themselves high estimation as exactly accurate registers of the total amount of electricity supplied. He would now have to refer to the provisional specification, because, notwithstanding the decision of Mr. Justice Wills, the question of disconformity was being raised by the defence in this case.

Mr. CRIPPS said he did not raise disconformity in the ordinary sense of the term, but on the construction of claim 3, and in connection with that, the provisional specification was important.

Mr. MOULTON then read portions of the provisional and complete specification, and, with the help of Mr. SWINBURNE, explained to his Lordship the various parts of the meter on a model constructed by the plaintiffs according to the specification. Mr. Moulton then read the claims from the specification. The first claim, he said, really claimed the type of meter now before the Court, and so it had been held by Mr. Justice Wills. The plaintiffs alleged the infringement by the defendants of that claim and of the third claim (in the amended patent). As to disconformity that only turned on the question of whether a man had put in a claim for one invention and produced another. But a man had time to improve upon the claim that he put in originally. He had nine months during which to work out and improve upon what he claimed in his provisional specification. The provisional specification was merely a kind of enlarged title. The title improvements in electricity meters might have become to be too vague, and something more definite might be wanted. The defendants said that if having got this specification anyone went over the field of electrical literature and picked out a bit here and a bit there and a bit elsewhere they might find possibly that people had previously held the ideas of Mr. Hookham. Well, that was very likely. But Mr. Hookham was the first to make a practical affair of this meter and had rightly claimed it. The Bradford Corporation in their character as electricity supply dealers were the defendants in this case, and he would produce now to his Lordship one of the meters which they used. It looked very different from that of the plaintiffs. They had chosen the arrangement in which the current went through the field instead of the armature and they must have an armature which had a constant current. (Mr. Swinburne here again mounted to the Bench and explained the apparatus to his Lordship.)

Mr. MOULTON, continuing, said that what the Bradford Corporation had done was that they taken the vertical spindle which his patent claimed. Their brake disc was revolving between the poles of two permanent magnets with large polar ends close together. The plaintiffs said that the Bradford Corporation instrument infringed both the first and the third claims for large and permanent magnets. Mr. Justice Wills had realised that Hookham was the first person to make a meter of this kind; that he was justified in claiming it and although the question was very different it was only a variant—only taking one of the alternators just as in this case the defendants were taking one of the alternatives set out in the specification.

Mr. Justice FARWELL: But how far can you monopolise principles which are known?

Mr. MOULTON said they could not do so, but if one took certain principles and made a practical meter then he could claim for that and within that claim he was entitled to prevent another from infringing.

Evidence was then called.

Mr. GEORGE HOOKHAM, examined by Mr. Walter, said he had devoted a good deal of time to the study of electricity, and he was the patentee of 4,225* of 1887, relating to this electric meter. At the time of his taking out that patent there were only two practical meters in use, or on the market (the Edison electrolytic and Aron). So far as he knew there was no meter of the character described in his specification. The meter which was before his Lordship (referred to throughout the case as G.H. 2) was constructed in accordance with the drawings in the specification. That was one of the first meters constructed by him. The drawings were made from such a meter. (The Witness pointed out and explained to his Lordship the different portions and other devices of the machine). In order that the apparatus should meter correctly the field or armature had to be constant. In the apparatus in question whether constancy could be maintained depended upon the whole construction of the magnetic circuit. He found when he came to work on the subject that he could get a powerful field with steel which was absolutely permanent. It was necessary to have a practically closed magnetic circuit.

Mr. WALTER: May I put it that until you pointed out the conditions of a powerful permanent magnet such things had never before been made?—So far as I know they had not been made before nor the possibility of them believed in.

It is alleged that that specification is insufficient to enable a person to produce the required result. What is your view?—I think it is perfectly sufficient.

Examination continued.

He had sold a considerable number of the meters in the actual form described in the specification. So far as he knew they gave satisfaction as meters of electricity. He did not think he had submitted that form of meter to the Board of Trade.

Mr. WALTER: It is suggested that your invention is not new. So far as you know was your invention as described in the specification new at that date?—Yes, so far as I know.

What is the nature of the current supplied upon the Bradford circuits?—It is continuous or direct current at a constant voltage between 200 and 250 volts, but I am not sure.

Cross-examined by Mr. Cripps.

On the circuit such as the Bradford it made no difference whether it was a current meter or an energy meter.

Mr. CRIPPS: When you have a current meter it is specially designed not to take any notice of change of pressure?—Oh no; it is not specially designed for that. It is designed on the assumption that changes of pressure need not be taken any notice of.

Cross-examination continued.

It was not quite true to say that if the potential varied at any time his current meter would not chronicle it in any way. The object of the energy meter was to chronicle differences in pressure as well as differences in current, whereas his meter chronicled current only. In order to have a correct current meter, it was necessary to have an electromotor with constant, or nearly constant, field.

Assuming you want to measure variations in energy, it would be destructive to that to have an electro-motor with constant, or nearly constant, field?—The Witness said that would be so.

The WITNESS, continuing, said that he did not claim to have discovered eddy currents or the saturation of the magnets. He did discover

† An abstract of this patent will be found on page 101 of this issue.
‡ *The Electrician*, Vol. XXXVIII., pp. 601, 617, 622, 665, and 839.

Digitized by Google

how to make a powerful and constant magnet. In 1887 witness took out a specification for an energy meter. It was subsequent to his specification for a current meter.

Mr. CRIPPS; Supposing the electromotive force did not vary, the only force they had to measure was the current force. But if you wanted to measure the electromotive force, the defendants' meter would do it and yours would not?—Yes; that is so.

Cross-examination continued.

The defendants only passed the shunt currents through the commutator, and witness passed the whole current. He had permanent magnets. It was necessary to have the magnets powerful. The same form of magnet would be powerful whether it was applied to the motor or the brake. It depended upon the shape of the armature and the shape of the brake. In his case he had the armature and brake moving in the same field.

Is not the form of magnet which you refer to in your specification the form known as the built up or compound magnet?—I am not familiar with those names.

Cross-examination continued.

What he referred to was a magnet with added pole pieces.

Mr. CRIPPS: Just look at the following passage in your specification: "In place of electromagnets, as described and represented, I prefer using for smaller installations permanent magnets, a number of bar magnets being substituted for the electromagnets represented in the drawings, though I may use magnets of other shape or configuration." Now, is not this model which I have got in my hands a model of what you call there a number of bar magnets with iron pole-pieces, which are represented by the black wood (handing the model to the witness)?

The WITNESS: Yes. That would produce the result that mine produces.

Cross-examination continued.

No magnet of that form was used by the defendants. The defendants' was another shape or configuration. The term "pole pieces" used in his specification meant pole pieces, or added pole pieces, as distinct from the magnet itself. There was nothing in his specification which showed that he contemplated a magnet without an added pole piece.

The WITNESS stated that the principle of having an electrical generating machine "having a constant field and working on constant resistance, or, stated generally, by any arrangement involving the motion of a conductor relatively to a magnetic field, the strength of the field being maintained constant and the current in the conductor being proportional to the rate of rotation" had already been explained and described by a great number of people. The merit he claimed was applying the principle to the electric meter. His first claim was for an electricity meter for measuring currents, consisting of an electro-motor with constant field. For the purpose of measuring currents a constant field was necessary. If you wanted to measure energy, a constant field was destructive.

Mr. CRIPPS: What I want to call your attention to is that there is no arrangement in the defendants' meter which is anything like the arrangement that you have adopted in the motor part of it?—I am afraid that is hardly for me, but if you ask me I should say it is covered.

Cross-examination continued.

The meter as used at Bradford had a practically constant field.

Mr. CRIPPS: Do let us consider. Supposing there is a variation in energy, the meter would show it because the field would be inconstant?—Certainly.

But if you have no variations in your electromotive force and do not want to measure it, then you might get the same result with one machine as with another?—That is our case.

But if you want to measure energy, and have to measure it, then the defendants' field is a field machine and it is essential that it is inconstant?

The WITNESS: Yes, but Bradford does not want to measure energy.

Now in order to get constancy of field you either have a saturated magnet or a permanent magnet?—Yes, or I give a third method: "In electrical circuits in which the electromotive force is practically constant this degree of saturation in electro-magnets is not essential." Then I go on to say what I prefer.

Cross-examination continued.

So far as the defendants are concerned in connection with the motor part of their machine they neither had a saturated magnet nor a permanent magnet. He could not agree that they had no device whatever for obtaining a constant field. Bradford took the device of putting it upon a constant-pressure circuit; the meter itself, he agreed, had no such devices.

I am taking the meter itself?—But you see we only attacked it where used at Bradford where the field is practically constant.

Cross-examination continued.

An electric brake with a permanent magnet was in no sense new at this time. He knew of a case where a disc was used with an electro-magnet brake, but he did not remember one with the permanent magnet.

The witness was next questioned as to Siemens' energy measurer.† The brake power there was given by a fan revolving in some fluid. There was a series motor in connection with that fan.

I am putting to you that the motor there, as far as the motor is concerned, is exactly the same as the defendants'—there is no difference?—Yes. I believe that is so.

Mr. CRIPPS: Could not anyone taking Siemens' energy measurer and putting in the electric brake for the fan have produced an energy motor like the defendants?—Well, apparently Siemens could not. Of course it seems easy when it is done.

I put it to you: Was not the practical difficulty simply the invention of a suitable form of commutator?—Oh, dear no. Certainly not; there were other difficulties.

† Described by M. Deprez in the *Lumière Electrique*, Vol. II. (1884), pp. 223 and 224. For an abstract of this article see p. 103 of this issue.

Your attention has been called to Ayrton and Perry.† Now I put it to you that every feature in the defendants' energy meter is found in Ayrton and Perry, and the only difficulty that Ayrton and Perry did not get over was the friction point?—I should say that almost every possible form is mentioned in Ayrton and Perry, and of course the defendants make a selection, but I think it has almost logically exhausted all the possible forms in theory.

The WITNESS stated that he took exception to the learned counsel speaking of the Ayrton and Perry meter. There was no Ayrton and Perry meter.

Then take the Ayrton and Perry specification. Does not that describe everything that is necessary and describe it accurately for the energy meter, except that it does not show a way of getting over friction? I should have read it through from that point of view. I do not remember that it shows how to get the constant field from the brake in practicable form. I do not remember that, but that is the first point that occurs to me.

I am putting to you that in Ayrton and Perry you find everything that we have in the defendants' meter, except they did not get over the difficulty of friction which has been got over in the defendants' meter?—You find a sort of suggestion of everything. I do not think you find anything that helps you towards making a meter, except a bare theory of the Foucault brake, which of course was a great thing to point out from the point of view of theory, I am not diminishing from the value of that from the point of view theory, but it did not help people to make a meter.

Cross-examination continued:

Speaking from momory he should have said that in 1887 Ferranti's was hardly a practical meter.

Shown Munro's specification‡, WITNESS said that as regarded the theory of a meter, apart from the point of constancy of pressure, the theory was in that specification, but there was a great absence of detail. It did not even refer to the element of friction as a disturbing element, and probably the patentee there did not know of it at the time. The friction in the instrument, which was made under that specification, was fifty times greater than in his (Mr. Hookham's) meter.

Questioned as to Handford's (Edison)§ specification, WITNESS said that as regarded the motor part of that, the principle was the same as his.

Mr. BOUSFIELD: That is to say that you have to have a suitable electro-motor rotating in a constant field?—I do not see any provision for procuring a constant field. He believed that Handford wanted to have a constant field. So far as he had a constant field he would have the driving force proportionate to the current.

The WITNESS stated that the brake portion in Handford was quite different to his.

Mr. BOUSFIELD then referred witness to an American specification of Weston. This he said was a current indicator, and instead of metering ampere-hours, it indicated by a pointer the number of amperes passing at the moment. There was a little cup in the middle in mercury. Instead of the current being able to rotate that cup continuously, it was only able to turn it until the resistance created by a spring was sufficient to balance the turning force of the current. For that he wanted a highly constant field. In a second specification of Weston's there was what was called an electrical meter, and his plan of measuring the current passing was to cause a flow of mercury from one vessel to another. In order to get that he wanted to have a powerful and constant magnetic field. The witness added that a motor with an armature working in a constant field was not his (witness's) invention. That was found in two or three of the prior apparatus. Weston had the idea of large pole pieces closely fronting, and the idea of winding his electro-magnets so that they were saturated. It was true that Handford wanted a constant field. His objection was that the winding such as Handford had shown would not give him a constant field.

Supposing I wanted to make a Handford meter, and for the purpose of getting the field constant I wind the magnets to saturation, thereby simply using the knowledge open to the world, and outside my specification, do you say that your second claim would prevent my doing that?

The WITNESS replied that he did not think the saturation had occurred to this patentee. He thought it was a question of mere law. As a matter of fact he did think that his second claim would prevent it.

Mr. BOUSFIELD asked the witness what he thought would be the result if he took a Siemen's energy meter with a disc and used a known magnet to brake it?

The WITNESS replied that if it turned out to have a constant and powerful field substantially in the way or according to the instructions he gave, he should say it would be an infringement.

Mr. BOUSFIELD: Here is a known type of magnet, and it turns out to be strong enough and constant enough to do it. You say it comes within what you taught the world?—Yes, that is what I say.

Cross-examination continued.

There was no instruction in Deprez for producing an absolutely and powerful magnet. He thought there was a great deal in putting the pole-pieces close together. To preserve the strength of a magnet it was necessary to keep the magnetic circuit closed. The closer the poles of a magnet were together the more complete was the magnetic circuit, and the less loss took place.—That was common knowledge.

In answer to his lordship, Mr. BOUSFIELD said that the defendants' case was that magnets of the dimensions of the plaintiffs' were used for similar purposes before date of plaintiffs' specification.

Mr. BOUSFIELD said that the makers of the defendants' meters had had considerable research as to the different and best processes of manufacture for the magnets. They relied upon the ageing process for the purpose of getting the magnets constant. They had them magnetised up to the highest point. Then they were put on some rotating instrument

† See Abstract on page 103 of this issue.

‡ *See* page 103 of this issue.

§ *See* page 103 of this issue.

Digitized by Google

which passed through boiling water and out of it again and again. That let down the magnetism some 15 per cent. In the ageing process the plaintiffs found that they got the magnets practically constant. (To the Witness). In doing that we are not borrowing from anybody.

The WITNESS: No; on the contrary, I think you are doing what is absolutely unnecessary. I have had very large experience in this subject.

Mr. BOUSFIELD: Is it possible to make a meter for alternating currents according to the description given in your specification?—I think so.

The WITNESS added that he had never made a meter for alternating currents according to this specification. He could make such a machine on another plan, and more cheaply.

Mr. BOUSFIELD: I put it to you that there is no sufficient description here, combined with the common knowledge at the date, to enable you to make an alternating meter which would work?—Yes, certainly it would. Take a Siemens meter, and put on a brake disc, and if you follow my directions you well have a perfectly suitable meter for alternating current. Do that, and the thing is done.

Mr. FLETCHER MOULTON re-examined the witness, dealing first with junior specifications. There were, he said, two classes of meters, those which measured current and those which measured total power.

A spur wheel can be used for measuring current, can it not?—If I understand properly what a spur wheel is, it would have no break at all.

Suppose you have a spring applied to resist rotation, then Monro's apparatus is capable of indicating current?—Witness agreed. That could be done either by a spur wheel or a disc. That was, however, a case of indicating current, not adding up supply.

In reply to the judge, the learned counsel said he was suggesting that Monro was dealing with an indicator of current, and not with a meter at all.

WITNESS explained that the angle through which the wheel was turned was a measure of the current passing at the moment.

Mr. Justice FARWELL suggested that it would be better to take this evidence from an expert, which the witness did not represent himself to be.

In further examination, the WITNESS said that neither Monro, Handford, Ayrton and Perry, nor the two Weston's specifications, would have enabled persons in their day to make a practical meter. He did not think that Jamin's paper would put people in the way of making constant strong magnets, such as he himself referred to. For suitability for use in a meter the union of constancy and power was necessary. To the best of his knowledge, no one had before pointed out how suitable permanent magnets for an effective meter could be obtained. In his own specification he might have two magnets, of which one was strongly magnetised and the other not so strongly magnetised. With regard to reversal of function of the armature and the field it was, generally speaking, quite possible to take your choice whether, you had the current through the field or through the armature.

Does that apply to a circuit of constant potential, such as an electric light circuit? Is there then any difficulty in using either?—No.

WITNESS considered that in the case of a current which would vary greatly, the small current would be through the armature. In that case the saturation would be of the stationary part. Apart from the cost of energy there would be no difficulty in that at all. Supposing for any reason it was desired to get saturation in the working part it was by no means impracticable. A person reading the Hookham specification would, he believed, be able to do it if he chose to.

Mr. MOULTON intimated that he would only examine the witness on a few points, and the others would be taken in detail from subsequent witnesses.

The WITNESS declared that Ayrton and Perry had not within his knowledge made a meter at the time of witness's publication.

How many years was it before they succeeded?—One of them, Prof. Perry, made a meter I think in 1890.

WITNESS said that in the same year he took out a specification for an energy motor, but that was before the publication of his first specification. The two were convenient, and were at the same time in the Patent Office.

In regard to the infringing meter, was it an infringement inasmuch as the current passing through the armature is with a constant potential?—Yes. There was a shunt coil in the field. A little current ran through that quite independent of the lamp circuit.

So there is a complete motor apart from the lamp circuit?—Certainly.

If, said the WITNESS, in order to get a good contact so as to have no resistance at the commutator brush you had excessive pressure, that gave friction. It was so important to get good contact that it had to be sought, even though it gave friction. He could not see that it made any difference whether the pole pieces were cast in one or joined on. His original meter was a practical meter in its time, and not surpassed in accuracy by any motor meter, though surpassed by the Edison deposit meter, and possibly by the Aron meter, which worked by clockwork, but not by any self-containing meter.

Mr. JAMES SWINBURNE, examined by Mr. Walter, was the next witness. He said the importance of meters was fully realised long before 1887, though actual demands for instruments were small. As early as 1884, inventors were endeavouring to find a meter. The essential requirements of a meter were that it would measure electric energy, or in practice the electric current; it must have a proper range, and of course be accurate throughout that range. It was useless having a meter which was useful for ten lamps and useless beyond 12 lamps, and the meter must start with one lamp. In those days there was difficulty in getting a meter which would start with one lamp when there was a large installation. As regards the use of magnets, he knew of no one before Hookham who designed permanent strong magnets, although fairly strong and fairly permanent magnets might be found in various places. Hookham's use of mercury he thought was new. Mr. Hookham was right in pointing out the advantage of having a constant field, and, if he might respectfully say so, took a very intelligent means of carrying it out.

Do you know what meters were, in fact, in existence at the date of Hookham's specification?—Ferranti's; I remember working at his meter from 1884 onwards. I do not know whether the Aron meter was at work at this time. I do not think there was any meter in actual use.

There was the Edison deposit meter. That, said the WITNESS, was not in use in this country, though in extensive use in the United States. The Ferranti meter was not of the Hookham type at all. The motor part should have followed the square law, and the brake part of it ought to have followed the square law, but neither followed any law accurately. Ferranti's meter had a fairly good range. It worked on entirely different lines than Hookham's meter.

The witness was taken *seriatim* through the specifications prior to Hookham's. Munro employed a Barlow's wheel. There was nothing in his Paper to show that he knew anything about the action of a brake. Munro, in his opinion, did not teach anything as regards the operation of a meter, and would not enable a person to produce a practical meter. Ayrton and Perry pointed out the use for a meter of a motor, and their specification gave a full explanation of the theory of what he would call a straight line meter, but it did not carry the matter beyond theory.

I think we learnt from the patentees in the witness box at the last trial that they had not produced a practical meter?—We did hear something of the kind, I believe.

In your view would this enable anyone to make a practical meter on the lines laid down?—I do not think it is necessary to go into hypothesis at all; it did not. There is not enough disclosed.

As regards Handford's specifiation, the WITNESS said he found no instructions given respecting the saturation of the magnets. It taught the manufacturer of a meter nothing. Abel's specification was not for an ampere-hour meter, but was a meter recording the flow of current at any particular moment. This gave no indication as to the strong magnetisation of the magnet. Yeatman's specification of 1885 concerned the motor only, and not the brake, and told nothing about the brake. It did not teach the world how to manufacture a meter that would mete. Weston had got the field-magnets. It did not teach Hookham's invention; of course, it went in that direction, but, in fact, the knowledge was not Weston's. It was common knowledge at that date that saturated field-magnets could be used as instruments. Weston, in his other specification of 1885, might have had a pious wish to obtain an ampere-hour meter, but it did not work. The apparatus would not work at all unless it had a very considerable current passing. As regards meter construction, it contained nothing to lead anyone to a successful meter.

Constancy of field had been used in measuring instruments before, but not in meters?—Yes.

WITNESS said Siemens had suggested for purposes of a brake a device of fluid friction. Deprez gave to the world nothing more as to the constructional part than Ayrton and Perry; no direction as to how the strength and permanence of the magnets should be obtained. Deprez did not disclose plaintiff's invention. There was nothing to be learnt from Rankin and Siemen with reference to powerful constant magnets. In his opinion the researches of Jarmin did not disclose the Hookham invention. He also thought that Dredge's specification did not disclose Hookham's invention. He was acquainted with the meter used at Bradford. The motor was a straight line motor, and the brake a straight line brake—permanent magnets from permanent magnets—It followed the straight line law and gave strength and constancy to the field. That followed in his view the instruction indicated by Mr. Hookham. At Bradford there was a constant pressure supply upon the mains used at Bradford; the character of the field would be constant, and the little auxiliary force would be constant. The meter could not work properly without a constant field. The meter in use at Bradford measured ampere-hours.

This closed Wednesday's proceedings.

Yesterday Mr. Swinburne was cross-examined by Mr. Cripps, and as a third witness for the plaintiffs Mr. Dugald Clerk was called. After he had been examined by Mr. Walter and cross-examined by Mr. Graham, Mr. FLETCHER MOULTON said that he had Prof. Boys in Court, but as he had already called three witnesses he did not wish unnecessarily to increase the bulk of the evidence, and asked whether the defendants on their side would limit their evidence to three witnesses. Mr. Cripps, however, would give no such undertaking.

Mr. WALTER then read the *verbatim* report of Mr. Justice Wills' judgment in the case of Chamberlain and Hookham *v.* Johnson and Phillips (see *The Electrician*, Vol. XXXVIII., p. 839) in which the validity of the Hookham patent was upheld. This closed the plaintiffs' case.

Mr. CRIPPS then opened the case for the defence, and was speaking when the Court adjourned. A full report of yesterday's proceedings will be included in our next issue.

We give below an abstract of the Hookham patent, No. 4,225 of the year 1887, which is alleged to have been infringed.

An interesting point, though it may have no direct bearing on the case, is that the patent which was applied for in March, 1887, has been amended twice by the patentee during its life; once in 1889, and then again in 1895. To show where the alterations have been made we print the first additions between asterisks, the later additions in italics, and the corresponding deletions in square brackets.

The title of the patent is "Improvements in Electricity Meters, Parts of which Improvements are applicable to Dynamo-Electric Generators and Motors."

The PROVISIONAL SPECIFICATION is as follows:

"My invention consists of the improvements hereinafter described in electricity meters, parts of the said improvements as hereinafter pointed out being also applicable to dynamo electric generators and motors. I

Digitized by Google

will describe my invention as applied to an electricity meter. My said electricity meter consists essentially of an electro motor with constant or nearly constant field, the armature carrying the current to be metered and an electric brake, consisting of a mass of metal in the form of a disc, cylinder or other figure of rotation rotating in a magnetic field in such a manner as to have "eddy" or so-called "Foucault" currents generated in it. When all other work done by the motor is negligible compared with that done against "eddy" currents the speed of rotation of its armature is directly proportional to the armature current.

"The electro motor may be of any convenient kind or form.† It may, for instance have a drum, ring, or disc armature. Or it may consist of a simple solid disc or cylinder rotating between magnetic poles. In the latter case, however, I prefer to‡ use two thicknesses of metal in the disc or cylinder, the one carrying the current to be measured to be insulated from the other except near the centre. And in order to confine the current to a narrow field the said disc or cylinder may be slit in directions at right angles to the motion in the field, or instead of a disc or cylinder so slit insulated wire or metal strips may be used.

"The electric brake may be formed by the armature itself or it may be attached to the armature so as to rotate in the same field, or it may be independent of the armature and rotate in a separate field or a separate brake may be used in addition to an armature brake. In order that other work done by the motor may be very small compared with the work done on the electric brake, special means to reduce friction are adopted. If the axis of the motor armature is horizontal the spindle is supported on friction§ wheels and if vertical or nearly vertical on hardened points, and in both cases I use mercury contacts or commutators where practicable.

"If the spindle of the motor is horizontal, I form a double‖ commutator, consisting of two sets of insulated spokes or projections placed side by side, each set dipping into a mercury trough, the mercury troughs being connected, one with each terminal of the machine. Each commutator spoke is put in connection with the one opposite to it on the other half of the double commutator, so that the mercury troughs, though both on the same side, act as ordinary brushes act when placed on opposite sides of the commutator. If the spindle is vertical, I take the advantage of the high surface tension of mercury in virtue of which it may be made to stand above the level of the vessel containing it. The ends of wires or metallic strips from the vertical armature can thus cut the mercury without touching the vessel.

"When I use a motor consisting of a simple solid disc or cylinder, I may, in order to economise magnetising force, corrugate the disc or cylinder in concentric rings, and form the magnet poles to correspond in a manner analagous to that described in the provisional specification of the application for patent made by me on January 6, 1887, No. 187, and thereby not only lessen the resistance of the non-magnetic space, but in this case also increase the efficiency of the driving current.

"If in any case it is found impracticable to render friction or other disturbing causes inappreciable I may 'compound-wind' the magnets of the motor, or if they are separate, of the electric brake, or both.

"In cases where iron is used in the armature or the electric brake, I may so dispose the magnets as to counteract gravity, and thereby lessen friction, or if the spindle is vertical I form it of iron, and place it in the axis of a solenoid having a similar action.

"For alternating currents the magnet cores, and if of iron the armature core, must must be be finely divided into wires or metal strips.

"The revolutions of the meter are registered by means of counting apparatus of an ordinary type.

"The double commutator, and the corrugation of the disc or cylinder hereinbefore described, are applicable to dynamo electric generators and motors."

The commencement of the COMPLETE SPECIFICATION is identical with the first four paragraphs above (to the word "vessel"), except for the slight alterations mentioned in footnotes. It continues:

"When I use a motor consisting of a simple solid disc or cylinder I may, in order to economise magnetising force, corrugate the disc or cylinder in concentric rings, and form the magnet poles to correspond, and thereby not only lessen the resistance of the non-magnetic space, but also increase the efficiency of the driving current. If in any case it is found impracticable to render friction or other disturbing causes inappreciable, I may 'compound-wind' the magnets or armature of the motor, or, if it is separate, of the electric brake.

"In cases where iron is used in the armature or the electric brake, I may so dispose the magnets as to counteract or partially counteract gravity, and thereby lessen friction. For alternating currents the magnet cores, and, if of iron, the armature core, must be finely divided into wires or metal strips.

"The rotations of the axis of the armature of the meter are registered by means of counting apparatus of an ordinary type.

"The double commutator and the corrugation of the disc or cylinder and pole pieces hereinbefore described are applicable to dynamo electric generators and motors."

The way in which the "said invention is to be performed" is next described, with reference to drawings. The armature consists of a series of metallic sectors, making up a circular disc with radial slits, the sectors being insulated from one another by these slits. These sectors do not extend to the axis of the machine. They are carried by a circular disc which is mounted on the axis, and constitutes the brake referred to above; but the sectors are insulated from this disc. The method of interconnecting these sectors is next explained; and then the commutator and the mercury troughs, in order to avoid the friction of a brush or spring upon the two opposite sectors and to effect the transmission of the current through mercury which is practically frictionless."

The specification continues: "If for any reason I desire to make the axis of the meter vertical, I may make use of the high surface tension of mercury to form a nearly frictionless commutator by means of two cisterns of mercury, filled so completely that the surface of the mercury at a little distance from the side of the vessel stands higher than the edge of the vessel. In such case the segments of the commutator will revolve horizontally, and then the commutator need not be divided, but may consist of horizontal sectors moving in one horizontal plane."

The Foucault brake is then described as follows:—

"The brake consists of a metallic disc, *b*, preferably of copper, fixed on the axis *a*, and consequently rotating with it. As the said disc *b* travels between the pole-pieces *f*, *g*, electric currents (commonly known as 'eddy' or 'Foucault' currents) are generated in the said disc *b*, the resistance they cause to the motion of the disc being proportional to its velocity. It is of importance to increase as far as possible the magnitude of these eddy currents. In order to do this I form the pole-pieces *f* and *g* with grooves in them radial or nearly radial to the axis of rotation of the armature, as shown in Figs. 1, 2, and 3. The said grooves increase the retarding action of the brake disc *b*. They may be either made in both of the pole-pieces *f* and *g*, as shown, or only in the pole-piece *f* nearest the brake disc *b*. Though these grooves are advantageous, they are not essential, as both the pole-pieces may be without grooves."

Next, the method of reducing the friction of the axis on its bearings by an arrangement of "anti-friction wheels and adjuncts" is described. Methods of standardising the meter by varying the resistance of the shunt-circuit, or by using a bar of iron to partially short-circuit the magnetic field, are mentioned; and it is added that the latter idea is applicable when permanent magnets are used.

The inventor does not limit himself to the use of an armature divided into sectors, as a continuous disc may be employed in which the current travels only between the axis and periphery. The latter arrangement, he says, although inferior in sensitiveness to the former, may be conveniently employed when heavy currents are to be measured. The specification then goes on:—

"In the meter described and represented the main current passes through the armature and the shunt through the field magnet, but similar results may be obtained by reversing this arrangement, in which case the use of iron in the armature is preferable.

"In order to enable the meter to measure current the field must be constant, or else the armature must be of constant magnetic power, and the current to be measured must in such latter case pass round the field magnets. To obtain this constancy in electro-magnets they must be saturated, and the magnetising force and the dimensions of the core must be so proportioned as to secure this. The constancy of the field in which the brake moves (in the case in which it moves in a separate field) may be secured in an analogous way. *In electrical circuits in which the electromotive force is practically constant this degree of saturation in electromagnets is not essential.* But I prefer to have as field magnets both of the electro motor and of the brake permanent magnets, as they can be made to be very powerful and very constant by the following means.

In place of electromagnets as described and represented I prefer using for smaller installations permanent magnets, a number of bar magnets being substituted for the electromagnet represented in the drawings, though I may use magnets of other shape or configuration; but in all cases in which I use permanent magnets whether for the field of the motor, or of the brake, the pole-pieces should have their surfaces very large compared with their distance apart as represented in the drawings, so as to form a narrow slit in which the disc armature revolves. When this is done the permanent magnets are practically constant, and this arrangement is essential to the constancy of permanent magnets unless the disc is of iron, which is objectionable on other grounds. The power and constancy of these permanent magnets are increased by magnetising them when in position, which is easily done by wrapping wire round them and passing a powerful current through the coil so formed. *I prefer to make the ratio between the area of the pole-pieces and the distance apart of the said pole-pieces at least 70 times as great as the ratio between the sectional area of the steel magnets and the length of the said magnets.* . . . . Although I have described only that form of electric brake which I prefer to employ, yet I do not limit myself to that form, as it may be replaced by any electrical generating machine having a constant field and working on constant resistance, or stated generally by any arrangement involving the motion of a conductor relatively to a magnetic field, the strength of the field being maintained constant, and the current in the conductor being proportional to the rate of rotation. The armature itself may be made to act as an efficient brake, and the brake disc dispensed with by making the sectors of thick copper and of considerable breadth as compared with the teeth or projections of the pole-pieces. Although I prefer generally to use only one pair of poles, I may use a second pair of similar poles symmetrically disposed on the opposite side of the axis.

The following are the claims, the amendments being shown as stated above:—

First.—An electricity meter for measuring currents consisting of an electromotor with constant field arranged substantially as hereinbefore described and illustrated in the accompanying drawings, the said electromotor being combined with an electric brake also moving in a constant or nearly constant field, preferably the same field as that in which the armature rotates, substantially as herein described and illustrated in the accompanying drawings.

[Secondly, Compensating for magnetic drag or friction, or both, by compound winding either the armature or the magnets.]

[Thirdly] *Secondly*—In electricity meters the obtaining a constant field either for the brake or the armature or both by the use of electromagnets of such construction and dimensions that they become saturated while in

† The complete specification has "of any of the ordinary forms now in use."

‡ The complete specification has "may" instead of "prefer to."

§ "Anti-friction" in the complete specification.

‖ The complete specification has "double or divided."

Digitized by Google

use in circuits of the kind for which they are designed, substantially as herein described.

[Fourthly] *Thirdly.*—In electricity meters the use, for the purpose of procuring a "powerful and" constant magnetic field, of permanent magnets arranged as described, with very large polar surfaces closely fronting each other "so as to form a narrow slit in which the disc armature revolves", whether the same be magnetised in position or otherwise, and the means described for regulating the same when or if necessary, substantially as herein described and in part illustrated in the accompanying drawings.

[Fifthly] *Fourthly.*—In electricity meters the construction and arrangement of parts forming a divided commutator making contact by means of mercury placed in insulated vessels substantially as hereinbefore described and illustrated in the accompanying drawings, and the use of the divided commutator in and in connection with dynamo machines or electromotors as described.

[Sixthly] *Fifthly.*—The construction and arrangement of parts forming a commutator making contact by means of mercury placed in insulated vessels, the axis of revolution of the commutator being vertical substantially as herein described.

[Seventhly] *Sixthly.*—Making grooves in the pole-pieces of the electro-magnet or permanent magnet of an electricity meter for the purpose of increasing the action of the brake substantially as hereinbefore described and illustrated in the accompanying drawings.

[Eighthly) *Seventhly.*—The method hereinbefore described and illustrated in the accompanying drawings of combining the disc armature or insulated sectors with the continuous disc constituting the brake.

[Ninthly] *Eighthly.*—The arrangement and combination of parts, hereinbefore described and illustrated in the accompanying drawings, for diminishing the friction of the rotating axis of the meter in its bearings.

[Tenthly] *Ninthly.*—An electricity meter, constructed substantially as herein described and illustrated in the accompanying drawings.

The original form of Hookham meter was described and illustrated in *The Electrician*, Vol. XXII., p. 369; a later pattern was described in Vol. XXXII., p. 220; and a short description of the 1897 pattern will be found in Vol. XXXVIII., p. 405.

The Thompson integrating wattmeter, which is the alleged infringement when in use on the mains of the Bradford Corporation, is a motor meter with a Foucault brake. The field coils carry the main current going to the lamps, and the armature, drum-wound on an ironless core, forms part of the shunt or pressure circuit. To overcome the solid friction, two fixed coils, auxiliaries to the field, are also connected permanently in the pressure circuit, and an inactive non-inductive resistance is added to bring up the resistance to the desired amount. Current is led to the armature through silver brushes resting against a silver commutator. An illustration of the meter, and a more complete description of it, will be found in Mr. Ricks' 1897 B.A. Paper, *The Electrician*, Vol. XXXIX., p. 574.

Among the alleged anticipations referred to in the evidence is an early Ayrton and Perry patent (No. 2,642 of 1832), "Contrivances for Registering the Amount of Work given Electrically to any part of an Electric Circuit in a given time." The following is an extract from the latter:—

"If now the only work done by the motor is done in overcoming fluid friction, or in causing magnets to revolve in front of metallic plates such as copper, or as in Arago's disc experiments, in all these cases the forces resisting motion are proportional to the velocity, and it is obvious that the number of revolutions made by the motor in any time is proportional to the electrical energy given to the circuit in that time."

The first claim in this specification runs as follows:—

"In measuring the total amount of energy given to an electrical circuit, the use of an electrometer whose fixed and movable parts have soft iron or else non-magnetic cores, wound respectively with a coil or coils of small resistance, through which the main current of the circuit passes, and a coil or coils of high resistance, through which passes a current proportional to the differences of potentials at the ends of the circuit in question, the motion of the motor being resisted by vanes immersed in a fluid or by any other resistance which is proportional to the velocity substantially as described.

The following is an extract from an early patent of John Monro for "Improvements in Electric Light and Power Apparatus" (No. 1,626, of 1882), a patent referred to during Mr. Hookham's cross-examination:—

"As a means of measurement of the electric current employed in lighting and for motive purposes, I employ an adaptation of a device known as Barlow's wheel. In this a horseshoe magnet encloses a disc of copper mounted on an axle, and when the current passes from the axle by the wheel to a pool of mercury into which the edge of the disc dips, such a disc rotates. This rotation is proportional to the strength of the current, and by fitting a suitable indicator or counter to the axle of the disc I can register the number of turns, and so graduate my indicator as to show amperes. To screen off the effects of extraneous magnetic influence, I enclose my ampere meter in a thick case of soft iron."

The patent alluded to as the "Handford" patent is an Edison patent (British Patent No. 2,675 of 1882), Handford being the English patent agent. It is for "Improvements in Electrical Meters, which Improvements are also partly applicable to Motors to be employed for other purposes," and the specification continues as follows:

"The said invention, relating to improvements in electrical meters, has reference to the use in combination with indicating or registering apparatus of what is herein designated a mono-electro-dynamic motor for operating or controlling the operation of such indicating or registering apparatus, which motor is a non-commutator or uni-polar machine, its inductive portion being a straight or one part conductor, through which the current passes in one direction only. This one part or straight inductive portion is in the translation circuit, or in a shunt therefrom around a definite resistance in the translation circuit; the electrical energy consumed in which circuit is to be measured, whilst the field coils or helices of the machine are in a multiple arc circuit. Means located in the translation circuit are employed for opening the circuit of such field coils or helices, when the last translating device is removed from circuit and for closing the circuit of such field coils or helices when the first translating device is placed in circuit. The motor is provided with devices for imparting to it a definite loading in combination with which may be used means for varying such load to compensate for variations in proportionate friction, this part of the invention being also applicable to motors to be employed for other purposes."

The meter is then described in greater detail with the assistance of drawings:

The "mono-electro-dynamic motor" is composed of an iron base which forms the back of the field electro-magnet of the machine, one pole of which is the upper end of the central core, while the other pole is formed by the ring, or a number of separate pole pieces, supported on cores rising from the iron base and surrounding the central pole piece. Both inner and outer cores are provided with wire bobbins. In the magnetic field in the annular space between the inner core and the surrounding pole-pieces of the outer core is located the revolving part. This is "preferably" a cylinder which may be of copper, and which is supported by a central pivoting spindle resting in a depression in the top of the inner core. The spindle passes through a guiding yoke and through the centre of the closed upper end of the cylinder, and is secured rigidly thereto. It is pointed, and is constructed of platinum or platinum iridium alloy, so as not to amalgamate with the mercury, with which the depression above referred to is partly filled. The revolving pivot or spindle is located in the translation circuit, and the mercury is used to make good and sufficient contact, in order to carry a powerful current without heating.

The lower end of the revolving cylinder is provided with means for maintaining contact with the mercury in a circular trough. This means is "preferably" in the form of fans or paddles, which dip into the mercury, and while maintaining the circuit complete, act to retard the movement of the motor, giving it a definite loading, or a definite amount of work to perform.

After describing other parts of the instrument and accessories to it, and the manner in which it is to be connected up, the specification continues:—

"In order that the rotating shell may so perform its work that the speed of rotation will be directly proportionate to the current, the paddles upon the cylinder must be correctly proportioned and arranged in a proper manner. Since the meter may be made of quite large size, and when so made will have a large initial friction, it is preferred for large size meters to make the cylinder paddles loose and provide means for varying their dip in the mercury in proportion to the speed, in order to make the speed of rotation of the cylinder directly proportionate to the current."

The claims are:—*First:* In an electrical meter the combination with indicating or registering apparatus, of a mono-electro-dynamic motor, operating or controlling the operation of such indicating or registering apparatus; and having its inductive portion in the translation circuit, or in a shunt therefrom, around a definite resistance in the translation circuit, the electrical energy consumed in which circuit is to be measured, a multiple arc circuit including the field coils or helices of such motor, and means located in the translation circuit for respectively opening and closing the circuit of such field coils or helices when the last translating device is removed from circuit and the first one placed in circuit, substantially as hereinbefore described.

Second: A mono-electro-dynamic motor, in combination with means for giving such motor a definite loading, and means for varying such load to compensate for variations in proportionate friction, substantially as, and for the purposes hereinbefore described.

The following is the official translation of the article by M. Marcel Deprez in *La Lumière Électrique* (Jan., 1884, p. 223) on the Siemens energy measurer, alluded to in the case:—

"Mr. Siemens has exhibited at Vienna an instrument designed to measure the energy absorbed by any apparatus whatever using an electric current. It is composed essentially of a small dynamo electric machine of the Siemens type, of which the primary and secondary are quite free from iron. The primary takes the form of a galvanometer bobbin (cadre) wound with thick wire in which the current to be utilised passes. The secondary is, on the contrary, wound with very fine wire, and is connected in shunt with the main circuit; the brushes of the commutator are connected one with the source, the other with the end of the circuit in which are placed the apparatus for utilising the current. Lastly, the axis of the secondary is provided with wings which revolve in any liquid, such as paraffin oil or any other insulating liquid, which fills the whole apparatus. Any counting device whatever registers the number of turns which the secondary makes in a given time, and from this number of turns the inventors consider they can deduce the quantity of energy absorbed by the main current.

"It is easy to show that this is incorrect, and that this apparatus does not at all make known the quantity of energy absorbed by the useful circuit unless the difference of potential between the two extremities of this circuit remains constant, in which case a simple measurer of intensity would suffice. Indeed, let us designate by i the intensity of the current which passes through the secondary when equilibrium is established.

"I the intensity of current passing through the primary when equilibrium is established.

"E the difference of potential between the brushes of the secondary.

"e the electromotive force developed in the secondary when it revolves with an angular velocity equal to unity, and the primary is traversed by a current equal to unity.

"R the resistance of the secondary.

"w the angular velocity of the secondary.

"When the secondary revolves it develops a counter electromotive force proportional to the speed and to the intensity of the electric field of the primary, that is to say, to I this electromotive force is expressed by ewI, and the current i then determined by the equation

$$i = \frac{E - ewI}{R}.$$

Digitized by Google

"On the other hand, the primary being traversed by I the mechanical effect exercised by the primary on the secondary is proportional to Ii from well-known laws of electro-dynamics, which can be applied here, because this instrument contains no magnetic masses. This couple, proportional to Ii, would have the effect of increasing the speed until the counter electro-motive force of the secondary balances the difference of potential between the brushes, if the same rotation of the secondary does not develop, owing to the wings, which turn in paraffin oil, a mechanical resistance proportional to the square of the speed. When this resistance balances the couple Ii we have

$$Ii = Kw^2 \text{ (K designating a constant)};$$

but we have, replacing i by its value, $Ii = \frac{EI - ewI^2}{R}$,

whence $$Kw^2 = \frac{EI - ewI^2}{R},$$

whence we infer $$w = \frac{-eI^2 \pm \sqrt{e^2I^4 - 4kREI}}{2kR}.$$

The angle described by the secondary in time dt is wdt, and during a time t $\int wdt$ we have

$$\int \frac{-eI^2 \pm \sqrt{e^2I^4 - 4kREI}}{2kR} dt,$$

while the quantity of energy absorbed usefully in the same time is

$$\int EIdt.$$

"The two integrals cannot be equal, and in consequence the number of turns of the counter expresses something quite different from the quantity of energy absorbed. It is probable that the inventors of this instrument have considered the counter electromotive force developed by this apparatus as negligible, because it contains no magnetic masses, and it turns slowly. Indeed, even admitting this hypothesis, the equations are simplified and we have

$$i = E/R, \quad Ii = kw^2 = EI/R,$$

whence $$w = \frac{I}{\sqrt{kR}} \sqrt{E},$$

and $$wdt = \frac{I}{\sqrt{kR}} \sqrt{E} dt.$$

Whence it follows that in this case the number of turns of the secondary would be proportional not to $\int EIdt$, but rather to $\int \sqrt{E} Idt$, from the integral of which one can never derive $\int EIdt$. This instrument is then useless.

"I am now going to show how it is necessary to modify it to obtain the desired result. In place of providing the axis with wings turning in a medium whose resistance is proportional to the square of the speed, let us attach to it a copper disc revolving between the limbs of a permanent magnet, and dispense with the paraffin oil completely. The rotation of the disc between the poles of the magnet will have the effect of developing in the interior of the disc induced currents following a well-known law, which I formerly applied in my magnetic speed-indicator, exercising on the magnet a magnetic force proportional to the first power of the speed. We have then

$$Ii = k'w = EI/R,$$

whence $$\int wdt \frac{I}{k'R} = \int EIdt,$$

which solves the problem.

"In order to make this solution more rigorous, it would be necessary, in addition, to reverse the arrangement adopted by M. Siemens, that is to say, to put the thick wire on the secondary and the fine wire on the primary, It would then be the latter which would be connected in shunt with the main circuit."

This article is commented on as follows by F. Uppenborn, jun., in the *Centralblatt für Elektrotechnik*:—

"In this relation we have already shown that Siemens' instrument gives incorrect measurements, since it is pre-supposed that the friction is proportional to the first power of the speed, while notwithstanding, as is known, the coefficient of the second power is unduly large. . . . . What we say briefly in words, Mr. Deprez says more precisely in his careful calculation. Meanwhile we would call attention to one consideration, which, if it has not entirely escaped the attention of Mr. Deprez, yet is not mentioned in his interesting Paper. It is, namely, in general to lay stress on the attempt to relieve more delicate measuring instruments from the performance of their own inherent work. But if this cannot be effected, then care must be taken that the measuring and measured forces be great in comparison with the forces coming otherwise into play. If we apply this law to the instrument under consideration, it results that one must then endeavour to diminish the frictional resistance as much as possible and to make as great as possible the force consumption of the Faraday disc."

Knowles v. Isle of Man Tramways and Electric Power Co.

In the Manx High Court, on Monday, the hearing of this action was commenced. It was brought by Mr. W. L. Knowles, late engineer to the defendant company, to recover £1,183, alleged to be due for salary and commission. Mr. Browne, for the company, admitted £33 was due in respect of salary, and said the company had been and was willing to pay the amount at any time. As to the claim for £1,150 commission at 1½ per cent. on the cost of construction of the Ramsay section of tramways, he asked for particulars, and said there was never any agreement to pay that or any other commission. The hearing was adjourned.

Heyl Dia v. Edmunds and Others.

In the Court of Appeal last week before the Master of the Rolls and Lords Justices Rigby and Collins, Mr. Clare mentioned this case, which was an appeal by the plaintiff from a decision of Mr. Justice Kekewich. Counsel said that the plaintiff had come to terms with the defendants, and had paid their costs, and he therefore asked leave to withdraw the appeal. Mr. Russell, for the respondents, said he assumed the appeal was abandoned. The action was one to restrain defendants from divulging a secret process.

Their lordships gave the leave asked for, and the appeal was accordingly withdrawn.

City of London Electric Lighting Co. v. Corporation of London.

The judgment of Mr. Justice Farwell declaring the validity of the electric lighting contracts acquired by the City of London Electric Lighting Co., Ltd., was referred by the Court of Common Council to its streets committee, who yesterday brought up a report recommending that the City solicitor be instructed to lodge an appeal against the judgment. This report was carried by a majority of 86.

PARLIAMENTARY INTELLIGENCE.

COUNTY OF DURHAM ELECTRIC POWER BILL.

The Committee appointed by the House of Commons to consider electric power bills resumed its investigation into this bill on Friday.

At the opening of the proceedings the CHAIRMAN (Sir J. Kitson) stated that the Committee would accept the recommendations in the report of the Joint Committee of 1898 on electrical energy generating stations in the following respects, viz.: Compulsory powers for acquiring sites for generating stations and land for pipes and mains therefrom, and other works, whether within or without the area of supply, might as a principle be granted, but they were prepared to hear petitioners who objected to particular sites selected by promoters. In the case of powers being given for the erection of generating stations outside the area of supply, powers might be given for laying mains in streets leading from the generating station to the boundary of the area of supply, the local authorities having the option of breaking up and reinstating the streets at the undertakers' expense, and the Committee were prepared to hear petitioners who alleged that they were under special disadvantages arising from this provision with respect to the bill before them.

Mr. S. Z. DE FERRANTI, who was under cross-examination on Thursday when the Committee adjourned, was further cross-examined by Mr. J. D. Fitzgerald, Q.C. (for the District Councils of Hebburn and Felling). He said it was the case that the amount of electricity which he estimated that the company would supply was larger than that at present supplied by Sheffield, Newcastle, Blackpool, Leeds, Manchester, Edinburgh, Glasgow and Liverpool taken altogether.

In cross-examination by Mr. Baggallay, Q.C. (for the promoters of the Tyneside Electric Power Bill), WITNESS said he was not aware whether it was or was not proposed by the Durham Co. to place any limit on the dividends they might declare, or to place any restriction on price in the event of the profits going beyond a certain amount. He thought it would lead to the financial failure of both undertakings if districts within the Durham Co.'s profit area of supply were allowed to choose whether they should take their electricity from the Durham Co, or the Tyneside Co., nor did he think that that would be fair competition.

In re-examination, WITNESS stated that the class of business the company proposed to obtain did not at all correspond with the supply of one large city. If cities like Manchester and Liverpool could obtain the load which the company anticipated, they would be able to produce electricity at the same price, and therefore probably to rise to the same output.

Sir F. BRAMWELL, C.E., said the carrying out of the company's scheme would lead to the establishment of manufactures in country districts, and so to the avoidance of undue concentration of business and manufactures in towns. It would, he thought, have the same effect on manufactures as the extension of the mains of water companies had on building in the country. The Tyneside manufactories were distributed over both banks of the river. In one sense—that of the diminution of capital cost—the compactness of the area of supply was important to a company. He thought it would be prejudicial to the interests of the public if the Tyneside Co. were allowed to compete with the Durham Co. in the district bordering on the Tyne, because it would result in the southern part of the Durham Co.'s proposed area of supply being deprived of the means of supply.

Mr. J. TODD, chairman of the Durham Electric Lighting committee, said he had been authorised by his Council to give evidence in support of the bill. Electricity was used in some collieries in which he was interested, and it there cost from 4d. to 6d. per unit. If the company obtained their powers the proprietors would take current from them. In a colliery there would be both a night and a day load. Pumping could be done very largely by electricity, and pumping operations were carried on chiefly at night.

Ald. HINDMARSH said that the Gateshead Corporation had entered into a provisional agreement with the Durham Co. for the supply of electricity for lighting and traction.

Ald. ARMSTRONG (ex-mayor of Jarrow) said he was authorised by the Jarrow Corporation to support the bill. The Corporation attached the

Digitized by Google

greatest importance to the scheme because they wanted to provide cheap means of transit by tramway for the working classes, from the congested parts of the town near the river to healthier localities in the south.

Mr. STEPHEN SELLON, C.E., said he was interested in a number of tramway schemes in the County of Durham. By adopting electric traction it was possible for tramways to be worked at rates that would otherwise be out of the question. He was not interested in the County of Durham Co. except as a future customer.

Mr. W. L. MADGEN, one of the promoters, said he was well acquainted with the district covered by the bill, and had had a large share in determining what that district should be. Numerous industries were being carried on in the county, including engineering, quarrying, iron working, brick making, colliery work, &c. There were 20 local authorities in the proposed area of supply, and, with the exception of Felling and Hebburn, which had a joint population of only 34,000, they all assented to the proposals of the bill. It was certainly the case that the scheme of the promoters was to generate electricity, and a separate but allied company was to supply it. The advantage to the consumers lay in the fact that they would get electricity under more economical engineering conditions than would be the case if separate generating stations were put down in, say, Hebburn, or Felling, or Jarrow. Hebburn had a provisional order, but there were no means of knowing whether the local authority would carry it out. The promoting company was allied with the British Electric Traction Co., which had the means of obtaining any capital it desired. Its own subscribed capital was £1,300,000. He would prefer not to have a sliding scale inserted in the bill as to the price at which electric energy should be supplied to consumers. He would rather have the question dealt with by means of general legislation later on when more was known of the economics of the matter. Personally, however, he would not object to the insertion of a clause rendering the company subject to general legislation on this point.

The CHAIRMAN (addressing Mr. Moon, for the promotors) said: The Committee wish to know more about your substantiality—your power of carrying out the scheme. Supposing this great county were given over to you, they wish to be satisfied that you have the power and influence to raise the necessary capital. I would suggest to you that you should bring evidence directly before us on that point.

Mr. SYDNEY MORSE, solicitor to the promoters, said that certain financial companies had definitely undertaken to take up the whole of the capital of the scheme which was not taken up by the public. The capital was first to be offered to the public, and supposing the public did not take it all up the whole of the balance would be found by two existing companies—the British Electric Traction Co. (Ltd.) and the Brush Electrical Engineering Co. (Ltd.).

Mr. J. D. FITZGERALD, Q.C., for the Councils of Hebburn and Felling, said the question was whether these two thriving Tyneside towns were to be included in the scheme against their will. From their position they were suited for an electrical undertaking, and this was why the promoters were so anxious to include them in their area. The District Councils wished to be left free to deal with their own districts. The districts had a joint population of 40,000. Hebburn had already obtained a provisional order, and Felling was about to apply for one. The promoters were promoting another company, which was to distribute electrical energy to the consumers. The distribution company, which was about to get provisional orders for Jarrow and Gateshead, was going to sell to the consumer on the maximum demand system. When the distribution company got its provisional order there would be an end of all the boasted benefits which the present promoters were to confer on manufacturers, for electric energy would be sold to the immediate consumers at the highest price. This was the real upshot of this great scheme, which professed to have the object of reviving the trade of Tyneside, and enabling this country to compete with the United States and other trade rivals. The consumer would have to pay two sets of profits.

Mr. P. C. Major, chairman of the Felling Council, and Mr. J. Smale, chairman of the Hebburn District Council, gave evidence in opposition to the bill.

Mr. H. W. HANDCOCK, C.E., spoke of the suitability of the districts of Hebburn and Felling for an electricity supply works, and he thought that electricity could be economically generated there. He admitted that electricity could be more economically generated in one large than in a number of small generating stations, apart from the question of transmission. Copper was, however, now very dear, and the principle of saving coal at the expense of copper could not be carried too far. His estimate for an electricity scheme for Hebburn was £21,588 which would give a station capacity of 500 H.P. at the start, and plant could be extended as the demand increased. His estimate for a similar station for Felling was £15,500 with supply to consumers at 5d. per unit for the first 100 hours and 2d. per unit after. Current for motive power would be supplied at 3d. down to 0·9d. He estimated a load factor of 40 per cent. for public lighting and 18 per cent. for private lighting and motive power. The charge for street lamps would be £2. 12s. per 16 c.p. lamp per annum.

Mr. Handcock was the last witness against the Durham Co.'s bill and the Committee proceeded to deal with that of the Tyneside Co.

TYNESIDE ELECTRIC POWER BILL.

On Tuesday, Mr. BAGGALLAY addressed the Committee on behalf of the promoters of the Tyneside Electric Power Bill, not only stating his objections to the Durham Co.'s bill, but opening the case of the Tyneside Co., which the Committee agreed to hear before deciding on the preamble of the Durham bill. He remarked that the area of supply selected by the Tyneside Co. lay equally along both sides of the Tyne, and would take in the whole manufacturing and industrial parts of Tyneside, including Newcastle, Gateshead, Tynemouth, South Shields, Jarrow, Wallsend, Hebburn, Felling, and Walken. The Tyneside Co.'s primary object was to supply electric power for trade and manufacturing purposes, while the supply for lighting and traction was quite a secondary object. The difference between the two bills, therefore, was that the Durham measure was chiefly for lighting and traction, and the Tyneside bill was for trade purposes; with regard to the petitions, the objections of the local authorities related chiefly to the breaking up of streets, to competition with themselves, and to the question of whether they or a company should be able to make a profit out of the supply of electricity. He need not dwell on the question of the breaking up of streets nor on that of competition with the local authorities, as the company did not want to compete in the matter of distribution. If the local authorities wanted to make a profit out of the manufacture of electricity for trade purposes they wished really to step out of their legitimate sphere. There was a strong petition in favour of the Tyneside bill from a large number of manufacturers and traders, and among those who petitioned against it was the Newcastle-on-Tyne Electric Supply Co. (Ltd.).

Mr. ASHTON (a member of the Committee): The local authority is, under your bill, to have a veto on the retail supply of energy where it involves any breaking up of the streets. Do you propose that the local authority shall have a veto on supply in bulk as well as on retail supply?

Mr. BAGGALLAY: No, not if it is a bulk supply given to an authorised Parliamentary company. Counsel added that the Tyneside Co.'s proposed area of supply was 65 square miles south of the Tyne and 60 square miles north. The capital of the company was to be £1,000,000.

Sir A. NOBLE, C.E., vice-chairman of Sir William Armstrong, Whitworth and Co. (Ltd.), said that the promoters of the Tyneside Bill were all substantial local gentlemen of high position, and interested in industries of the Tyneside district. Armstrong, Whitworth and Co. employed in the Newcastle district about 20,000 or 21,000 hands. They used electric light themselves largely, and he had no doubt that, under certain circumstances, they would be very considerable customers of the Tyneside Co., and that if they could purchase electric energy they would use electric power to a much larger extent than if they generated it themselves. The passing and putting into force of the Tyneside bill would, he thought, prove very beneficial both to his company and to the neighbourhood. He was not aware that the Newcastle Electric Supply Co. already supplied electricity very largely for power purposes.

The CHAIRMAN: In view of the fact that there are two companies in the field, do you not think that the districts to the north of the Tyne would afford sufficient scope for an electric power supply company?—I should hardly think so. I should think that it could work much more economically if it had both the northern and southern sides of the Tyne.

Sir A. SCOBLE: Do you not think it would be fair to put it on a company as a condition that they should serve the lean as well as the fat parts of the district?—I do not think it would be unfair to stipulate that the company should supply the districts within a certain distance. I do not think it desirable that two companies supplying in bulk should compete in any particular area.

Mr. A. A. C. SWINTON stated that he was a promoter of the bill. He was connected with both the Scarborough and Cambridge Electric Supply Companies, which were both successful undertakings, and he had been responsible for laying down large electrical plants. He knew, as a matter of fact, that the Tyneside scheme was in the field long before that of the Durham Co., the former being cut and dried before the latter had been decided on. Some of the promoters of the Tyneside bill were interested in works on both sides of the Tyne. There were in the district manufactures of a nature that made it particularly desirable that there should be a good electric supply. That was particularly the case with the chemical industry, which required enormous amounts of electric energy. Such energy must be produced either by water or by coal. Very little could be done by water in this country, and Tyneside was, of course, an excellent place for obtaining a cheap supply of coal. The company proposed that it should be bound to supply energy in bulk at rates named in the bill to all authorities who applied for it. The distribution would be left to the local authorities. The charges were based on the Brighton system, but were not exactly the same as those in force at Brighton. For the first 200 hours of maximum supply the charge was to be 5d. per unit where there was a general supply, and 4d. per unit where the company supplied to a local authority in bulk for distribution; for a further quantity not exceeding 400 hours the price was to be 3d. per unit in the one case and 2d. per unit in the other; and for a further quantity exceeding 400 hours 1½d. and 1d. respectively. The promoters also proposed that there should be a sliding scale: the price was to come down as soon as the company had paid 10 per cent. In his opinion the proper system to adopt if the country was to be covered with these electric supply schemes was that the generating stations should be put down in the centre of a manufacturing area, and not on the edge of it, and that the different fields of supply should be allowed to grow until they met in what had been called a "lean" area. The promoters of the Tyneside scheme had no fear of the competition of the Durham scheme. They looked forward eventually to supplying hundreds and thousands of horse-power. He thought that in course of years the local authorities might wake up to the necessity of doing something of this kind if it were not done by a company, but he believed that they would be quite ten years behind private enterprise. He had no doubt whatever that if Parliament authorised the scheme it would be carried out with great benefit to the district.

Cross-examined by Mr. PAGE, Q.C., on behalf of the Gateshead Corporation and Whickham District Council: Under the bill the local authorities would be able to prevent the promoters of the bill from breaking up streets for any purpose whatever, except that of passing the mains through the district.

Digitized by Google

Cross-examined by Mr. RICKARDS, Q.C., for the Newcastle Electric Supply Co.: There were 19 local authorities in the proposed area of supply of the Tyneside Co., and the company hoped to come to terms with 17 of them. There would be no compulsion on the company to distribute electric energy retail in any district in which they had not obtained the consent of the local authorities. They were not, however, particularly anxious to distribute electricity retail. They would rather see distribution companies established and supply those companies in bulk. It was proposed to establish one of the company's generating stations at Wallsend, which would probably prove the most suitable site for the supply of the whole Tyneside district. The proposed site had been scheduled by the Newcastle Electric Supply Co. for the compulsory purchase, but he thought it would be too large for the company, and that it was of more importance to Tyneside Co. The promoters would probably adopt either the two-phase or three-phase system. The pressure would probably be 10,000 volts, but the question had not been definitely decided on. He would not be in the least surprised to hear that the Newcastle Supply Co. was charging less than the maximum charges given in the schedule to the bill, and he had no doubt that the charges actually made by the Tyneside Co. would be less than the schedule. A circular had been sent to every local authority in the district offering to supply at the following rates: Where the local authority distributed—for the first 100 hours of supply, 4d. per unit; for the second 100, 1½d.; and for the third 100, 1d. Where the company distributed—for the first 100 hours, 5d.; for the second 100, 2d.; and for subsequent hours, 1½d. They had also offered to supply consumers for motive power for manufacturing purposes for the first 100 hours, 3d.; and for subsequent hours, 0·9d.

By Mr. Squarey (for Tynemouth Corporation): It was the case that the Corporation of Tynemouth had an electric lighting order, but they had had the order for nine years and had done nothing. They were only now putting up a generating station.

Mr. HANS HAMILTON, on behalf of South Shields Corporation, asked whether it would not be unfair for the promoters to insinuate, by means of the private wayleaves into the districts where the local authorities had spent large sums of the ratepayers' money in establishing electric light undertakings. WITNESS replied that it was absolutely necessary for the purposes of trade that the large power companies should have access to the principal works.

Replying to Colonel Long (a member of the Committee), WITNESS said he did not think he was bound by the pledge given by Mr. Ritchie on the second reading of the four electric power bills that the companies would not go into a district without the consent of the local authority. He thought that that pledge applied more particularly to the Lancashire Bill. He was willing to take the chance of having the Bill thrown out on the third reading because he would not adopt that pledge.

Mr. WORTH, calcium-carbide manufacturer, said that the Company of which he was managing director contemplated establishing works on Tyneside, and had arranged with the promoters of the Bill for a continuous electrical supply of 5,000 H.P., at a price of a little over half-a-farthing per unit.

The Hon. C. A. PARSONS, one of the promotors of the Bill, said a great advantage would be derived from the use of very large steam turbine units, which would considerably reduce the first cost of the plant and also the coal consumption. It was most important that the North and South sides of the Tyne should be included in one supply district as they were practically on one footing as regards trade. The Bill made no provision for overhead wires, the intention being to put all the mains underground.

Yesterday (Thursday) Mr. Parsons was examined and cross-examined to considerable length as to the proposed charges to be made by the promoters. The chairman suggested that small consumers would be placed at a disadvantage by the fixing of excessively low rates to very large consumers—rates which were not really remunerative in themselves—WITNESS said that no protection of small consumers was provided in the bill with the exception of the sliding scale. He agreed, however, that it would be wise to protect the small consumer against undue preference.

The CHAIRMAN: I do not ask you to define how such protection should be afforded, but it is a principle of Parliament to protect the average consumer.

Mr. J. M. DAVIDSON, Managing Director at Newcastle of the United Alkali Co., said that the Company had works in Gateshead, Hebburn and Jarrow, employing on Tyneside about 2,500 workmen. The processes were at present carried out by steam-power, but if the company had the advantage of cheap electrical power it would be a very great boon to them. It was necessary to do everything they could to meet the competition of foreign countries, and he thought that there were many directions in which a cheap supply of electricity might be profitably employed. He earnestly hoped that the Tyneside Co. would be given the privilege of supplying electricity on the south side of the Tyne. He knew that the directors of the Tyneside Co. were men who understood their business, and were likely to establish their works on such a principle that the cost would be kept at the lowest possible point. They were people who were resident in Newcastle, who had an enormous stake in Neweastle, and who would be perfectly good for any bargain to which they attached their signature.

Mr. N. COOKSON, managing partner of Cookson and Co., one of the largest lead manufacturers in the country, with works at Tynemouth, chairman of the Wallsend and Hebburn Coal Co., and one of the promotors of the Tyneside Co.'s bill, said that the measure was supported by the largest manufacturers in the district, and if it were passed its financial success was, he thought, assured.

Sir BENJAMIN BROWN, chairman of R. and W. Hawthorn, Leslie and Co., engineers and shipbuilders, of Newcastle and Hebburn, having also given evidence in support of the bill,

The Committee adjourned till to-day (Friday).

CHARING CROSS AND STRAND ELECTRICITY SUPPLY BILL.

The Committee of the House of Commons, presided over by Mr. A. H. Brown, further considered this bill on Friday last. Mr. Worsley Taylor, Q.C., on behalf of the London County Council, asked the Committee to throw out the bill on the ground that the promoters had selected the most important thoroughfares in which to lay their mains, and that there was not the slightest necessity or justification for this selection. Various local authorities also objected to the scheme, chiefly on the ground of the interference with traffic which it would cause, and a number of witnesses were called on this point. The Committee ultimately found the preamble proved.

LONDON UNITED TRAMWAYS BILL.

On Friday the House of Commons Committee, presided over by Sir U. Kay Shuttleworth, considered this bill for powers to construct about 18 miles of electric tramways in the county of Middlesex. The only opponents were the Middlesex County Council and certain frontagers along the proposed routes.

Mr. BALFOUR BROWNE, Q.C., for the promoters, said it was a very important scheme in the interests of the western suburbs of London. The London United Tramways had already an extensive system of lines in West London, running from Hammersmith Broadway to Kew Bridge, with powers to carry a tramway to Hounslow. They had also a line along the Uxbridge-road to Acton and Ealing. These lines were at present worked by horses, but within a short time would be converted to the overhead trolley system. The company had powers to construct several connecting lines, and the Kew Bridge to Richmond line was also their property, but did not at present form part of the general system. On the completion of the company's generating station in July next the whole of the lines would be operated electrically. The proposals of the bill were to extend the line from Acton through Ealing to Hanwell, and from Heston and Isleworth through Twickenham and Teddington to Hampton Wick. The opposition of the Middlesex County Council was based upon a suggestion that at some time or other they would, in conjunction with the London County Council, carry out a scheme of tramways for themselves. But the promoting company were in possession, and the County Council were not the purchasing authority.

Mr. CLIFTON ROBINSON, general manager of the company, said the electric cars would accommodate 80 passengers in place of 36 to 44 in the horse cars. The adoption of electric traction at Stockton had led to an increase of passengers carried in one year from a million to eight millions, and a like increase had resulted in other cases. The proposals of the bill would increase the company's mileage from 21 to 39. They at present carried 10,000,000 passengers a year, and anticipated an increase to 40,000,000 or even 50,000,000 if the system was completed as now proposed.

At this point the Committee decided that the County Council must confine its opposition as regarded the preamble of the bill to the question of interference with the roads and bridges under their control, they having no *locus standi* on the question of the desirability of the construction of the lines.

Lord ROBERT CECIL (for the Council) then intimated that, under the circumstances, they did not think it would serve any useful purpose to prolong the opposition, and would therefore reserve their right to appear in the House of Lords against the bill.

The Committee, having heard witnesses and counsel for the frontagers at its sitting on Tuesday, decided to pass the preamble of the bill, subject to certain conditions—viz., first, all curves must be improved; secondly, as far as possible 9ft. 6in. must intervene between the footpaths and the lines; thirdly, where two footpaths did not exist the Committee must be satisfied as to the provision of a second in case of building taking place; fourthly, the Committee must be satisfied that a double line was not required where a single line was proposed.

HUDDERSFIELD CORPORATION TRAMWAYS.

In the House of Commons on Tuesday, on the order for the consideration of this bill as amended, Sir J. WOODHOUSE moved that it should be recommitted to the former committee, and that that body should be instructed to consider and report as to the expediency of reinserting in the bill the power to construct tramways to places outside the borough. The Committee had deleted that power from the bill on the ground that it was intended to appoint a joint committee to consider the subject of municipal trading, but this was not a question of municipal trading. Huddersfield originally undertook the working of its own tramways because they wold otherwise have been idle, a company having tried and failed, and no other lessee being forthcoming. In 1898 one of the suburban districts obtained a provisional order to construct tramways, but leased them to Huddersfield, which was the centre for the district, and other suburbs asked to be connected with the borough lines as well. The question was solely one of convenience and good government. The Huddersfield Corporation proposed to go into those districts at their special request, and the only opposition came from the Lancashire and Yorkshire Railway Co., on the ground of competition. He submitted to the House that it was not within the purview of the Government or of the House to refuse to municipalities that which had been granted year after year for years.

Lord E. FITZMAURICE said it was never intended that the Committee on Municipal Trading should put a veto on trading in the supply of gas, water, and tramways, but that it should deal with alleged excesses of municipal trading in other directions.

The PRESIDENT OF THE BOARD OF TRADE (Mr. Ritchie) said the Committee was debarred by the Standing Orders of the House from

Digitized by Google

sanctioning tramways outside the borough, but their position was that if the House thought they ought to reconsider their decision apart from the Standing Order they were willing to reconsider it. He favoured the extension of tramways outside towns because to it they must look largely for a solution of the housing difficulty.

The motion was agreed to.

SOUTH EASTERN METROPOLITAN TRAMWAYS.

The Select Committee of the House of Commons, presided over by Col. Cotton-Jodrell, on Tuesday commenced consideration of a bill giving power to the South Eastern Metropolitan Tramways Co. to substitute electric for horse traction on their tramway running from Greenwich to Catford on either the surface contact or conduit system.

Mr. LITTLER, Q.C., for the promoters, said the enormous increase in the number of passengers necessitated the present application, as electric traction would be cheaper, afford an accelerated service, and allow an increase in the number of cars run. In nine years the London County Council would have the power of purchasing this line, but the company had come to the conclusion that even for that short period it would be worth while to provide electric traction. The capital necessary for that purpose would be in all £42,000—£33,000 in shares and £9,000 by loan. The South Metropolitan Gas Co. opposed the bill on the ground of danger to their mains from electrolysis, and the London County Council oppo ed the adoption of any but the conduit system, as did also the Lewisham Board of Works.

Sir W. H. PREECE said the road along which it was proposed to run was an ideal road for an electric line, as its width was 60ft. The reconstruction of the line would cost £14,000, the electrical equipment £12,000, the mains £2,000, and the cars £8,000, and £4,000 was allowed for contingencies. The company rather preferred the surface-contact system, which had many advantages, was absolutely safe and very workable. There was no practical example of the system in this country or elsewhere with insulated returns, but this company were very anxious to give it a fair trial. The board of Trade regulations would protect the Gas Co.'s mains from all danger of electrolysis. He admitted that the surface contact system had been replaced at Washington by the conduit system. Prof. Kennedy, however, had rather favourably mentioned the surface contact system, and they were convinced that it had advantages that warranted a fair trial being given to it. His opinion was that this company would not lay down this system without a twelve months period of probation. If the system were tried and failed there would remain the opening in the centre of the road, and the only expense would be the putting in of the conduits. The surface contact system was working satisfactorily at Monte Carlo, and it was also in use at Paris. There was no danger of electrolysis from tramways laid down under Board of Trade regulations. The cause of electrolysis was the use of the rails as returns. In the case of the South London line that had been mentioned; it was an old line and a standing disgrace to London, but the railway company were now making alterations.

Mr. JACOB ATHERTON gave evidence as to the overcrowded state of the tramcars at the present time, and the large number of passengers carried. The surface contact system would cost about £2,000 per mile less than the conduit system. The Board of Trade would have to be satisfied even though the present bill passed. The system had been tried in Washington (U.S.A.), and had for special reasons been exchanged for the conduit system. There were now in Paris being constructed lines on the surface contact system. When he found sound financial people ready to lay down the system and take all risks for six or twelve months, he thought it was worth while trying it. He had two offers before him, one from a German firm and one from an American company.

Sir JOHN WILLOX, M.P., Chairman of the Blackheath and Greenwich Electric Light Co., said his company had recently erected a large, new station, and had a quantity of surplus power available. They, therefore, proposed to supply the South-East Metropolitan Tramways Co. with the power necessary for the working of their line.

The Committee, on Wednesday, after hearing counsel, decided to pass the preamble of the bill.

Yesterday (Thursday) the committee proceeded with the consideration of the clauses of the bill.

On behalf of the Lewisham Local Board the committee were asked to insert words in the bill restricting the Tramway Co. to the use of the conduit system of electric traction; and by the London County Council to insert a clause rendering it obligatory for the company to obtain the assent of the London County Council to the system adopted, or in the event of such assent not being obtained, that the Council should have a right to acquire the line at the end of the company's term without paying anything in respect of the electric plant laid down.

Mr. CASTLE, Q.C., for the South Metropolitan Gas Co., asked the Committee for a protective clause in respect of the danger from electrolysis to their pipes and mains, and the right to make any alterations required for themselves. There was, he said, everywhere a desire to substitute electricity for horse traction on tramways, and the effect of the use of electricity would be to set free electric currents all over the place, the effect of which it was impossible to foresee. In the area of the South Metropolitan Gas Co. there had already occurred cases of electrolysis, and fusion had taken place between their pipes and the electric wires. They therefore felt bound to ask for the protection of Parliament. It had been argued that the Gas Co. were intruders on the public highway, and must take any risk necessitated by the electric tramway or the user of the public. But that argument was entirely wrong. The first right to the sub-soil of the roads was in the adjoining freeholders, and all that was granted away was the public user, and anything that interfered with the gas or water mains or the drains interfered with the amenities of the houses. Therefore the gas company were in their proper place, and anyone interfering with them was interfering with the adjoining proprietor's property. The Board of Trade might make regulations, but they were not efficient for the purpose. Sir W. H. Preece had put his hand on what was required in the case of these electric lines; it was not only regulation, but supervision from time to time. Accidents would occur here and there, electricity would escape, pass through moist soil, turn the water into hydrogen and oxygen, which would attack the iron and turn it into plumbago. The damage might amount to thousands of pounds in the case of a large undertaking like the South Metropolitan Gas Co. Sir W. H. Preece had said there would be no danger from electrolysis in the present case, but, if that were so, a protective clause would do no harm, but only make the Tramway Co. careful in laying down their system. The Gas Co. also desired that in any interference with their pipes and mains the works should be carried out by themselves at the Tramway Co.'s expense.

Mr. CHAS. CARPENTER, Chief Engineer to the South Metropolitan Gas Co., said the power given to the Tramways Companies under the Act of 1870, to make alterations in gas pipes and mains had never been exercised, because horse traction did not necessitate such interference. But in respect to electric traction the making of the conduits would require a depth of from two to three feet, and in some cases necessitate the shifting of the gas mains. The main that would in the present case be affected was a 2ft. 6in. high pressure main.

Mr. W. R. COOPER gave evidence as to the effect of electrolysis on iron pipes and said attempts had been made to protect the pipes by coating them, but such means had not proved to be of much value, and could not be applied to pipes already laid.

Mr. JAS. SWINBURNE said electricity damaged gas and water pipes by corrosion. The prevention of the leakage of electricity with the rail return system was a matter of degree. If the Board of Trade regulations were carried out, they would keep it down to a small extent. Escaping electricity would travel along a pipe until it met with a non-conductor, and then in leaving a pipe created corrosion, and salts of iron would be formed. With rail returns leakage could not be stopped altogether, moisture and salts were always present in the earth. In America were there were no rules such as those of the Board of Trade, electrolytic action was about four times as rapid as in England where a low pressure current was used. Insulated returns would be a perfect protection as leakage would be unlikely. The surface contact system was an experimental one, and he could not speak as to its electrolytic effect. He saw no reason why gas companies should not be compensated for damage done to their pipes. A proposal had been made in the United States to substitute earthenware pipes, but that was impracticable. To put insulated returns in tramways was difficult, and if Parliament insisted on them, it would cripple the tramway industry more than it would protect the pipes. The tramways should be allowed to use rail returns, but if they damaged other people's property they should pay for it.

After hearing counsel, the Committee decided not to restrict the tramway company to the conduit system, rejected the proposals of the London County Council, and also negatived the claim for compensation in case of damage by electrolysis to the pipes of the South Metropolitan Gas Co., but agreed that the Gas Co. should themselves have power to make any alterations of pipes or mains required, and inserted a proviso as to arbitration.

MANCHESTER AND LIVERPOOL EXPRESS RAILWAY BILL.

Owing to extreme pressure on our space we are compelled to hold over our report of the proceedings before a House of Commons Committee on this Bill, which was commenced on Tuesday and was continued on Wednesday and Thursday. The Committee adjourned until this day (Friday).

PARIS EXHIBITION NOTES.

(FROM OUR CORRESPONDENT.)

PARIS, *Tuesday, May* 8.

Perhaps the feature which calls for first comment in connection with the Paris Exhibition, 1900, is its quite phenomenal unreadiness, except in those sections devoted to the fine arts and to the amusement of the masses. Here some degree of completeness may be noted. Those whom duty calls to describe these events are accustomed to find displays of this character in the packing-case stage on opening days, but here, on the 8th of May, nearly four weeks after the official opening by President Loubet, a large part of the Exhibition can hardly be said to have even reached the packing-case stage. And it is subject for comment how far this state of affairs has been caused by the opening ceremony having been fixed for so early a date. In the course of a stroll through the spaces devoted to fixed and moving machinery yesterday, by dint of carefully picking one's way through the heaps of opened and unopened cases, railway trucks and engines, balks of timber, masonry and ironwork, and carefully avoiding the huge pits at every point awaiting the advent of heavy castings not yet apparently even on the spot, it was possible to sound those responsible for the erection of these machines on the causes for this backwardness, and several did not hesitate to blame the State officials for their precipitency in opening the Exhibition as early as April 14. To make things appear more forward

Digitized by Google

than was the case, much was done that had to be subsequently undone, the workmen were led to leave their work to join in the "festivities" which naturally followed the official opening, and so very much valuable time was lost which can never be regained. The exhibition is open, the public crowds in, and the work is interfered with in a dozen ways that would have been avoided if the opening had been deferred to, say, May 1. This is undoubtedly a main cause of the disappointment loudly expressed on every hand. It is this cause also which is at the bottom of the inextricable confusion which everywhere prevails. To provide pathways and points of vantage for the opening-day visitors, things were placed on one side, which, only too surely, it was impossible to find when they were required for use. I have somewhat laboured this point, as it is unquestionably an extremely serious state of affairs for all concerned, and renders a visit to the Exhibition at this time an absolute waste of time and money. The greatest sufferers will undoubtedly be those firms whose enterprise and farsightedness led them to push matters at the outset vigorously, and who now find their efforts abortive, as the only persons who come to see their exhibits, newly erected, running in most cases for the first time in public, and with all the "bloom" upon them, are a crowd of country holiday makers, with mouths agape, whose unstinted admiration is magnificent, but is not business, and it is from the business point of view that those who have sent masses of expensive machinery, apparatus or instruments must of necessity regard these international shows. And this is not to mention the damage caused to moving parts of machines from the clouds of dust and particles of timber and plaster flying in all directions from the work in progress all around. It is positively disheartening to witness the condition, from this cause alone, of some of the more forward exhibits.

Altogether, the state of affairs at this moment at Paris should prove a valuable object lesson to those who have the organisation of similar shows in the future, to delay rather than expedite the opening ceremonies. There is usually a lamentable want of method in shows of this nature, but at Paris this lack of method, and the sacrifice of the "educational" to the "entertainment" aspect of this vast display has led to fearful waste of energy, and must represent the loss of a colossal sum in hard cash.

A further complaint at Paris is the difficulty of obtaining skilled labour—masons, carpenters, bricklayers, painters, &c. A great effort should surely be made by the State officials of the countries where these international exhibitions are held to secure that an adequate supply of skilled artisans are at the disposal of exhibitors, many of whom come with their exhibits hundreds of miles, and are on arrival at an obvious disadvantage compared with their native competitors. This disadvantage, always present from the nature of things, is doubly felt when the supply is so noticably inadequate as is the case at Paris.

Up to Sunday, May 6, the Exhibition was favoured with a spell of fine dry weather, and this has, of course, facilitated operations. In fact, it is difficult to conceive what the condition of affairs would have been if the weather had been otherwise. On Sunday evening, May 6, about 5 p m., a heavy thunderstorm passed over Paris, and while it helped to lay the immense clouds of dust which the introductory windstorms had created from the mass of suitable material at hand, it caused much inconvenience to those employed in the erection of machinery, statuary, and buildings. The half-emptied packing cases in the open were soon deluged, the paths were pools of mortar, the railway track became a swamp, with the result that on the resumption of operations on Monday morning a good deal of extra labour was involved in clearing things; which proves how essential to the ultimate completion of this exhibition is yet another months or six weeks of fine dry weather. Without it the Paris exhibition of 1900 will not be ready till August.

Nickel Electroplating.—According to the *Electrical World and Engineer* of New York, in a Paper read before the March meeting of the Chicago Electrical Association, Mr. C. F. Burgess gave a solution of the difficulty of obtaining a thick layer of adherent nickel in electroplating. A peculiar molecular strain is set up within the nickel during deposition, which reaches a value when a certain thickness is reached, such that the layer detaches itself from the iron or other metal surface, or is easily removed by subsequent polishing. In the electrochemical laboratory at the University of Wisconsin experiments have been made in depositing nickel from the ordinary plating solution and under ordinary conditions, with the exception that an alternating current is passed through the vat in addition to the usual direct current. It was found that this had a marked influence on the character of the deposit, it being possible thus to obtain a coating as thick as desired.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Alleged Incendiarism.—At the Central Criminal Court last week Christian Maddock, engineer, was indicted for attempting to set fire to a pattern store belonging to the India Rubber, Gutta Percha and Telegraph Works Co., Silvertown, with intent to injure. Mr. Guy Stephenson, who defended at the request of Mr. Justice Lawrance, moved to quash the indictment. The facts set out in the indictment were that the prisoner placed on the inflammable wooden floor of the pattern store wooden pattern blocks covered with cotton waste, that he saturated them and the surrounding floor with methylated spirits, and placed a freshly-trimmed but unlighted candle in the midst. Counsel argued that the acts done by the prisoner might have been a preparation to commit the offence, but they did not amount to an attempt. The last act depending upon the prisoner must be done in order to constitute an attempt. Mr. R. D. Muir for the prosecution argued that all that was necessary to constitute an attempt was that the act done should be sufficiently proximate to the commission of the crime to manifest clearly what the intention was. In this case the prisoner's intention was clearly manifest by his acts. Mr. Justice Lawrance was of opinion that, as something remained to be done by the prisoner, and as there was no interruption, what the prisoner did did not amount in law to an attempt. He accordingly quashed the indictment.

Arbroath.—Mr. Mathew Buchan has been appointed consulting electrical engineer.

Barnsley.—The charge for electric current for motors has been fixed at 1½d. per unit. A new main is to be laid along the Pontefract-road at an estimated cost of about £1,000.

Barrow-in-Furness.—The accounts of the electricity department were submitted to the Council on Monday. The chairman of the Electric Lighting committee (Mr. Smith) said the electricity station had been working for 12 months. The capital expended was £32,540. 16s. 10d., and the revenue £2,630. There was a gross profit of £758, of which £735 was absorbed in interest, leaving £23 for sinking fund. The average charge for current for private lighting was 4·97d., and the cost of generation, &c., per unit 3·4d. On the recommendation of the Highways committee it was decided to enter into an agreement with the British Electric Traction Co. with reference to the conversion and working of the Barrow tramways.

Battersea (London).—The Vestry has decided, on the recommendation of their consulting engineer (Prof. A. B. W. Kennedy) to lay distributing mains on both sides of St. John's road. Petitions have been lodged against the London County Council's two tramway bills with a view to secure further amendments in the measures.

Bradford. The Electricity committee are inviting tenders for electric motors of 4½, 7 and 10 H.P. for one year. The electrical engineer (Mr. R. A. Chattock) has also been authorised to obtain motors exceeding 10 H.P., hitherto the limit, and supply same in cases were application is made for them.

Canterbury.—A report on the first year's working of the electricity undertaking has been presented to the Lighting committee by the town clerk (Mr. H. Fielding). The consumers connected on March 31 were 195, against 106 in 1899. The number of public lamps is 12 arcs and 213 incandescents. The revenue account shows a gross surplus of £1,913. 2s. 7d., which, after allowing for legal reserve, was sufficient to pay a dividend of 4½ per cent. on the capital expended (£34,000), and to place to reserve £468. 2s. 7d. Interest on loan amounted to £673. 12s. 8d., and sinking fund to £833. 9s. 11d., leaving a net profit of £406.

Chesterfield.—An inquiry will shortly be held into the application of the Council to borrow money for erecting electricity works. The charge for current has been fixed at 6d. per unit for public and private lighting, and 3½d. for power. Applications have been received for the equivalent of 4,713 8 c.p. lamps. There are also applications for 11 motors, aggregating 50 H.P., and as it is proposed to erect 50 arc lamps for street lighting, the original scheme will have to be enlarged.

Croydon.—An inquiry was held last week into the application of the Corporation to borrow £20,570 for electric lighting. The town clerk (Mr. E. Mawdsley), and the electrical engineer (Mr. T. H. Minshall), supported the application. Mr. Minshall said that the present loan was for extensions of mains and plant, £6,800 being for station plant, and the balance for cables and mains. The loan was applied for owing to the great increase in the demand for current. Up to 31st March, the supply was equal to 45,122 8-c.p. lamps for private, and 3,500 for public lighting. When the Corporation took over the undertaking there were 18,000 lamps for private and 2,000 for public lighting. The existing plant would only be sufficient to meet the demand next winter, assuming a normal increase, without any reserve. The new plant would supply about 15,000 8-c.p. lamps alight at one time, or about 20,000 connected. In all probability the new plant would not be available until the winter after next.

Future consumers of the electricity department are to be charged on the maximum demand system.

Digitized by Google

Dublin.—The electric tramway service between Inchicore and Westland-row has now been extended to Victoria Bridge over the Grand Canal Dock at Ringsend. The only route still worked by horse cars is that portion of the Sandymount line from Haddington-road to the Sandymount terminus on the Strand road. This horse service is likely to be a permanency owing to the railway bridge at the commencement of London Bridge-road being so low that trolley wires cannot be passed under it at such a height as will allow the electric cars to run beneath.

The receipts of the Electricity department for the past quarter were £3,167. 3s. 9d., an increase of £577. 7s. 2d.

Dunmanway (Cork).—The Rural Council have considered tenders for the electric lighting of the town. A local tenderer (Mr. John Atkins) offered to supply and erect the necessary generating plant for £1,000, to light the town until 11 p.m. by incandescent lamps, and to maintain same for £30 per annum provided he obtained permission to supply current to private consumers. Messrs. Robert Dawson and Co., of Stalybridge, through their representative (Mr. Hunter), also offered to submit a scheme, but no figures were given. Opposition to the proposed area of charge was raised. The Council passed a resolution in favour of electric lighting, but the matter is to remain in abeyance until the sanction of the Local Government Board has been obtained.

East Grinstead.—The General Purposes committee are to report upon the advisability of obtaining electric lighting powers.

Electric Auto Cars.—Sir Howard and Lady Vincent have engaged an Oppermann electrical victoria for the season.

Electric Tramways in the City of London.—At yesterday's meeting of the Court of Common Council a communication was read from the London County Council, stating that the Highways committee of that body had under consideration a proposal to introduce a bill seeking powers to construct tramways in London, in which it was proposed to construct a new line of tramway from Farringdon-road and Ludgate-circus, and asking the City Corporation to support the measure. Mr. Deputy Johnson said it should be made perfectly clear whether the tramways were to be worked electrically. Ultimately the matter was referred to the Streets committee, with instructions to fully report to an early meeting of the Court.

Failure of Electricity Supply.—At the Greenwich Police Court last week Mr. Kennedy gave his decision on the complaint against the London Electric Supply Corporation for failure to supply electric current to the premises of Mr. Shaddick, of the "Dover Castle," Deptford. Particulars of this case were given in our issue of the 27th ult. Mr. Kennedy held that the defendants' plea of *force majeure* did not apply. He was doubtful whether the company allowed sufficient time to overhaul the boilers, especially when they knew of the hardness of the water and that the boilers would not last many weeks. He did not, however, rest his judgment so much upon that ground as upon their taking Mr. Shaddick as a new customer when they knew that, through the failure of the Colchester firm to supply new boilers and their inability to overhaul the old, it was, to say the least, doubtful whether they could adequately supply Mr. Shaddick with current. The penalty was singularly inadequate, and therefore he must inflict the full penalty of 40s. in each of the seven cases with 20 guineas costs in the first case and 2s. costs in each of the others, making £35. 12s. in all.

Frome.—Messrs. Medhurst and Kitchin have been appointed consulting engineers to the Council.

Great Yarmouth.—The receipts of the electricity department for the past quarter were £1,767, and, after paying interest, sinking fund, and all charges, there was a clear profit of £65. The statement for the past year showed a profit balance of £437, against a loss of £57 on the previous year. The gross profit from 1895 to 1900 was £7,218, but the net loss was £1,522. The Wellington Pier and the Pavilion are being wired at a cost of £70.

Greenock.—Mr. E. S. Fedden, who was recently appointed electrical engineer at Sheffield, terminates his engagement here on Saturday, and will take up his duties at Sheffield next week.

Hammersmith (London).—The engineer and manager of the electricity department (Mr. G. G. Bell) submitted a report on the result of the past year's working to the Vestry on Wednesday. The consumers increased during the year from 275 (representing the equivalent of 19,390 8 c.p. lamps) to 464 (representing 26,365 lamps). The average number of lamps per consumer had decreased from 70 to 56. This was mostly due to the number of small flats in the parish which was wired, £3,375 were received for lighting and maintaining 150 public arc lamps, 63 additional arcs had been added since last report, 620,078 units have been supplied for private lighting, producing £10,274. 5s. 7d., which worked out at an average price of about 4d. per unit. The average lighting hours of the lamps had been increased from 840 to 900 per annum, but owing to the reduction of practically ½d. per unit, the annual revenue per lamp had gone down from 10s. 10d. to 9s. The total cost of generation, distribution, &c., was £7,764. 14s. 11d., or 2·05 per unit, a decrease of nearly ½d. per unit on last year, being 56·5 per cent. of the revenue, leaving a gross profit of £5,974. 0s. 10d., or 43·5 per cent. towards paying interest and sinking fund charges. The whole of the buildings, generating machinery, and distributing mains have been maintained in efficient working condition out of revenue. The result of the year's working showed a net profit of £1,615. 4s. 8d., after the deduction of interest and repayment of capital. The capacity of the generating station is equal to supplying a further 10,000 8 c.p. lamps, after allowing an ample margin to reserve.

Hampstead (London).—The Guardians are applying for a loan of £2,003 for electric lighting and other purposes. The Vestry have taken up a loan of £90,740 on account of £97,178 applied for for electric lighting, to be repaid within 42 years, and have decided that the cost of all plant and machinery covered by the loan which it may be necessary to renew or replace during the currency of such loan, shall be defrayed out of a special sinking fund or out of maintenance account.

Hull.—An inquiry was held on Tuesday into the application of the Corporation to borrow £42,000 for electric lighting extensions. The town clerk said that the total of electric lighting loans was £128,490. The present loan was required to meet the increasing demand for current. The undertaking was financially a success. Last year they made a profit of £1,924. 3s. 4d., which was carried to reserve which now amounts to £10,092. There was no opposition.

Imports of Electrical Goods into the United Kingdom.—The accounts relating to the trade and navigation of the United Kingdom show that the value of electrical goods and apparatus imported during April was £411,335 against £73,085 in the preceding month and £360,966 in April, 1899. The total for the four months ended April 30 was £1,801,538, against £1,546,025 in the corresponding period last year.

Islington (London).—An expenditure of £4,125 has been sanctioned for 25 transformers. The outlay will, however, only be incurred when the London County Council has sanctioned the borrowing of the money.

Kiel (Germany).—The Municipal authorities have decided to erect electricity works at an estimated cost of £35,000.

Leeds.—At present the Corporation are supplying current to 1,500 customers, representing an equivalent of about 110,000 8 c.p. lamps, an increase of 50 per cent. over the figures when the undertaking was taken over from the Yorkshire House-to-House Electricity Co., 18 months ago.

Leyton.—The Council have decided to lay down additional feeders at an estimated cost of £7,288, and the electrical engineer (Mr. F. Harman Lewis), has been instructed to carry out the work.

Light Railways.—In their annual report to the Board of Trade for the year ended Dec. 31, 1899, the Light Railway Commissioners state that during the year 37 orders were submitted for confirmation, and of these 18 were confirmed and one was rejected, as it was considered the scheme should come before Parliament, The remaining 18 are still under consideration. Of the 18 orders under the consideration of the Board at the date of the last report, 17 were confirmed, and one was withdrawn. Up to Dec. 31 last the Commissioners had submitted 88 orders in respect of 91 applications to the Board of Trade for confirmation. Of the 94 applications for the year 1898-1899 nine were withdrawn prior to, and three were rejected without, holding an inquiry. Of the remaining 82 applications 67 inquiries had been held up to Dec. 1, with the result that 47 were approved, two adjourned, one withdrawn, and 17 rejected. The Commissioners express apprehension as to their ability to deal with the great and increasing number of applications within the specified time. In 1897 48 local enquiries were held, in 1898 54, and in 1899 73, but the Commissioners were in considerable arrears with the applications.

Llanelly.—The British Insulated Wire Co. recently arrived at an understanding with the Council for the erection of electricity works and for the conversion and extension of the local tramway. Some difficulty has been experienced in arranging terms with the tramway company, and the Council now propose to exercise their rights of purchase, and as soon as the undertaking passes into their hands it will be handed over to the B.I.W. Co.

London County Council.—At Tuesday's meeting a loan of £10,000 for plant and machinery for the electric lighting scheme of the Poplar District Board of Works was granted, and a loan of £20,000 (on account of £40,000 sanctioned on March 27) was granted to the Shoreditch Vestry for electric lighting work.

The decision of the Light Railway commissioners refusing the application of the County Council for an order to construct light railways in London was discussed, and it was stated that the Highways committee will shortly report upon the course it will recommend the Council to take in regard to this important decision.

Longton.—It has been decided to apply for a loan of £28,500 for erecting electricity works.

Digitized by Google

Maesteg (Glam.)—The question of obtaining electric lighting powers is to be discussed at the next council meeting.

Municipal Loan.—The Ilford District Council are inviting tenders for a loan of £66,700 for electric lighting. Tenders to Chairman by the 16th inst.

New Maldon (Surrey).—A special committee has been formed to consider the electric lighting scheme proposed by Mr. F. J. Warden Stevens.

Plymouth.—An inquiry was held by Mr. A. P. Trotter, on Tuesday, into the application of the Corporation to borrow £20,000 for additional generating plant for electric tramway purposes. The town clerk (Mr. J. H. Ellis) stated that electric traction on the Ebrington-street section had been so satisfactory that the Corporation desired to extend it to the northern section of the tramways. The Local Government Board had already sanctioned a loan for the overhead equipment and cars for the Compton section, and the present loan was required for the provision of generating plant, boilers and pipes, accumulators and switch gear, underground mains, &c. At the Corporation's station at Prince Rock there was space for all the plant to be put in. He asked that the loan should be for 30 years. The borough electrical engineer (Mr. Rider) said the Corporation had already borrowed £18,000 for overhead equipment and bonding of the lines. The track already existed, but certain sections of it would have to be renewed with heavier rails to carry the electric cars. That, however, was provided for in the previous loan. Mr. Trotter remarked that the Board had adopted definite rules with regard to the repayment periods of loans. They allowed 30 years for buildings and land, 20 years for electrical equipment and 15 years for cars. Mr. Rider then submitted technical details of the proposed new plant, and stated that the length of the line was over 3 miles of single track. There was no opposition.

Private Bill Legislation.—The Charing Cross, Euston and Hampstead Railway, and the Wellingborough and District Tramroad Bills have been read a second time in the House of Lords. The City and South London Railway Bill has been read a third time.

Redditch.—An inquiry has been held into the application of the Council to borrow £8,000 for electric lighting. The clerk (Mr. G. W. Hobson explained that the present loan was required to meet excess expenditure and carry out extensions. There was no opposition.

Reigate.—The charges for current for private lighting have been fixed at 7d. for the first hour's maximum demand, and 4d. afterwards. The annual charge for public arc lamps is to be £18 per lamp.

Salford.—A special meeting of the Council was held on Monday to consider the report of the special committee recently appointed to investigate certain matters relating to the borough electrical engineer (Mr. C. L. Turner), and certain alleged irregularities in connection with plant contracts. The Committee was composed of the Mayor (Ald. S. Rudman), the Deputy-Mayor (Ald. W. Robinson), and Aldermen Hulland and Phillipps, and Messrs. E. Desquesnes, J. Higson, W. Stephens, and A. Worsley. The report stated that the Committee had held four meetings, at which in the presence of of Mr. Turner, the evidence of Mr. Haworth, chairman of the Electric Light committee; Mr. Bates, member of Council; Mr. Clirehugh, consulting engineer; Mr. Holt and others was taken. Mr. Turner had had the opportunity of asking these gentlemen questions, had subsequently made his own statement to the committee, and had produced such witnesses and documents as he thought fit. In August, 1898, Mr. Turner, as borough electrical engineer, was instructed by the Electric Light committee to prepare and submit plans for the new works and plant required. He did so, and in Dec. 1898, the committee advertised for tenders based upon these plans, &c. The Council, however, rejected the plans and specifications, and the tenders were not opened, but by direction of the Council, Messrs. Lacey, Clirehugh and Sillar were instructed to prepare a new set of plans, which were submitted and adopted in December. In the meantime, Mr. Turner appeared to have conceived that he had the right to appropriate to his own use and benefit a portion of some plans which had been thus rejected. These plans referred to a form of arrangement of pipework originally prepared by him under the direction of the committee, and, as he admitted, prepared at the cost of the Corporation and in pursance of his duty as borough electrical engineer. Without making known that intention to, or seeking the consent or advice of, the chairman of the Electric Light committee, he had a preliminary interview with a firm of patent agents at a date stated to be September, 1899. In the same month Mr. Turner stated that he had an interview in Manchester with a member of a firm of pipe makers, at which it was arranged that the firm in question should take up Mr. Turner's patent upon a royalty of 7½ per cent. payable to Mr. Turner, and in October an agreement was drawn up embodying that arrangement. In November instructions were given by Mr. Turner to the patent agents to secure provisional protection in his name, the official notification being dated Nov. 30 that the grant was registered as being applied for under date Nov. 22. The committee had, at Mr. Turner's request, compared the plans relating to his patent with those prepared by Mr. Clirehugh, and found that there was considerable similarity on a cursory examination, but Mr. Turner had pointed out that his plans disclosed an arrangement of valves and piping aimed at securing that any one of a series of boilers or its connecting steam pipe could be shut off without interfering with the supply of steam from the other boilers. Mr. Turner invited the committee to obtain expert evidence to establish the distinction, but the committee did not deem it necessary to enter further into the question of the validity of the patent, as the borough engineer had declared that Mr. Clirehugh's plans were different and did not effect the purpose for which he had a patent. If so, it resulted that the contractors would not have been chargeable with any royalty in respect of Mr. Turner's patent. The tenders were advertised in Feb. last, and the pipe-making firm already referred to applied and obtained specifications and information from Mr. Clirehugh's firm, and then addressed a letter, not to Messrs. Lacey, Clirehugh and Sillar, the proper persons, but to Mr. Turner, asking for the names of firms tendering for condensers and steam pipes, so that they might, as sub-contractors, submit prices for consideration. Mr. Turner in February, having obtained the desired information from Messrs. Lacey, Clirehugh, and Sillar—without, as they affirm, disclosing its object—supplied the names to the pipe-making firm, who subsequently issued a letter stating that they understood the person to whom it was addressed proposed to quote for the Salford steam-pipe and condensing plant, and pointing out that the pipe installation was in accordance with Mr. Turner's patent system, of which they were the sole licensees. The agent of the pipe-making firm had explained that he thought Mr. Turner's patent was adopted in Messrs. Lacey, Clirehugh and Sillar's plans. Questioned as to these matters, Mr. Turner stated that on receipt by him of the request for the names he saw Mr. Clirehugh, and said he had received the letter asking him to send all the names of intending contractors, and asked if he (Mr. Clirehugh) had any objection to that, and he replied that he saw no objection. Mr. Clirehugh's evidence was that no such statement was made, and that a simple verbal request was made to him by Mr. Turner for the names, without explanation, and he supplied them as a matter of course, having regard to Mr. Turner's official position. In concluding their report the committee expressed the opinion that Mr. Turner was not justified, without the knowledge and permission of his committee, in seeking a patent for work done by him on behalf and at the expense of the Corporation, who were his employers, and that there had been an unfortunate coincidence in the time of his securing a patent for pipework with the time when plans were being produced for contractors with the Corporation in his own department to tender for pipework; that Mr. Turner was not justified in supplying the list of names; that it was difficult to believe that he was not cognisant of what was being done by the pipe-making firm; and, finally, "that Mr. Turner has endeavoured to mislead your committee and members of the Electric Light committee (namely, its chairman and Councillors Haworth and Bates) on important matters of fact involved in the inquiry, with the result that he has lost your committee's confidence." A motion that the report of the committee be received and entered upon the minutes of the Council having been seconded and adopted, the Mayor moved—

"That, in the opinion of this Council, Mr. C. L. Turner has forfeited its confidence, and that he be required to resign his position as electrical engineer, and that three months' salary be paid to him in lieu of notice."

Ald. Mandley moved as an amendment that the electrical engineer be forthwith dismissed. Upon a division the amendment was lost by 28 votes to 12, and the resolution was then agreed to. Ald. Phillips said a letter had been written by a Manchester solicitor threatening the chairman of the Electric Light committee (Mr. A. Haworth) with legal proceedings. He, therefore, moved—

"That in case any legal proceedings are brought against Mr. Haworth in connection with the matter, the Council undertake to defend him."

Mr. Haworth said the action he had been compelled to take in this affair had been most painful. He had every confidence in the electrical engineer up to a certain point. The resolution was passed, and the Council adjourned.

Southport.—The Council on Tuesday decided to apply for sanction to borrow £40,000 for relaying the tram lines recently purchased from the Birkdale and Southport Tramway Co., and to provide the necessary electrical equipment.

Spalding.—As the Council are the owners of the gas works they have decided to oppose an application by a company for a provisional electric lighting order.

Tunbridge Wells.—The Lighting committee have engaged Sir W. H. Preece, at a fee of 50 guineas, to prepare a report as to the best means of preventing nuisance by smoke and vibration at the electricity works.

Underground Telephone Wayleaves.—The Marylebone (London) Vestry have given the National Telephone Co. permission to lay their wires underground.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers, or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

READY.

(Price 12s. 6d., by post, 13s. 3d.; Colonies, 14s.; abroad, 14s. 6d. (United States, 15s.)

"The Electrician" Electrical Trades' Directory and Handbook for 1900.—In addition to the well-known features of this Directory and Handbook (all of which have been carefully revised and brought quite up to date) a large addition has been made to the Handbook Division, including a Digest of the Law of the Telegraph and Telephone, for the use of municipalities and companies contemplating applying to the Postmaster-General for a Telephone Licence. This section of the book now includes the new model form of Licence issued by the Postmaster-General, the Telegraph Acts and Orders passed by Parliament in 1899, and other information in connection with this the latest development of electrical enterprise. The huge sheet tables of Electric Light and Power and Electric Railway and Tramway undertakings of the United Kingdom have been made quite complete. These sheets form a most complete record of electrical engineering progress in connection with electricity supply and power and traction applications. The Directory Division has been carefully extended and corrected, and is the most reliable list of firms and persons engaged in the electrical and allied industries ever compiled. A number of additional sketches of the careers of well-known electrical experts have been added to the Biographical Division, together with many new portraits. The new volume is the most complete and correct book of its kind ever published in any language.

"The Electrician" Reading Case.—To hold four numbers of the journal. Strongly bound, 1s. net; post free, 1s. 4d.

"Magnetic Induction in Iron and other Metals."—By Prof. J. A. Ewing. Price 10s. 6d. net. *New Edition (Third) now ready.*

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free. The book deals with the important subject of localising faults in electric light and power cables; and the various methods of insulation testing are here collected and discussed.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves." A Review of the Work of Hertz and his Successors.—By Dr. O. J. Lodge, with a large number of illustrations, bringing this latest application of electrical science quite up to date. New and Enlarged Edition, 5s. nett. *Now ready.*

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free. The authors give in a clear and concise manner a good summary of the general principles of electrical science.

"The Incandescent Lamp and its Manufacture."—By Gilbert S. Ram. Price 7s. 6d., post free. The principles underlying the manufacture of the incandescent lamp are carefully and fully dealt with in this volume.

"The Centenary of the Electric Current, 1799-1899."—By Dr. J. A. Fleming. Price, paper covers, 1s. net, post free 1s. 3d.; strong cloth, s. 6d., post free.

"Motive Power and Gearing for Electrical Machinery."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free. In this comprehensive work an account is given of the scientific principles and modern practice in the use of engines for dynamo driving, not only for isolated power plants, but also for public electric lighting and power stations. The various forms of gearing in the power station and for electric motors are also dealt with; and the book contains, in addition, numerous tables giving exact data of the equipment and working of electric power stations.

"The Manufacture of Carbons for all Electrical Purposes."—by Francis Jehl. 10s. 6d., post free. This is a practical handbook, giving a complete description of the art of making carbons for electric lighting, electrodes, &c., with particulars of the various gas generators and furnaces used in carbonising. The work also contains particulars of the cost, &c. of erecting and working carbon works, and plans of a model factory.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. *New and Cheaper Edition*, 6s., post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free.

"Submarine Cable-Laying and Repairing.—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. This work gives a detailed technical summary of modern practice in manufacturing, laying, testing, and repairing submarine telegraph cables.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free. The author treats fully both the theoretical principles of the art of electrolytic separation of metals and the practical rules and details of technical application on a commercial scale. The work is adapted to the use of the manufacturer as well as the student.

"Electromagnetic Theory."—By Oliver Heaviside. *Vol. I.*, 12s. 6d. *Vol. II.*, 12s. 6d.

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth. also ready. Price 7s. 6d., post free. Propsectus on application. This is a complete treatise on the theory and construction of drum winding, and of commutators for closed coil-armatures, together with a *résumé* of the principal points involved in their design, and an exposition of armature reactions and sparking.

"The Alternate Current Transformer."—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. Vol. I.—*New Edition.* Price 12s. 6d., post free, Vol. II., price 12s. 6d., post free, is also ready.

"The Students' Guide to Submarine Cable Testing."—A new edition of this book, by Messrs. H. K. C. Fisher and J. C. H. Darby, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

Glasgow Corporation require tenders for indiarubber-covered and lead-covered branch cables and carbons for one year. Specifications, &c., may be obtained from the engineer (Mr. W. A. Chamen), 75, Waterlow-street, Glasgow, and further particulars are given in an advertisement. Tenders to the town clerk (Sir J. D. Marwick) by 19th inst.

Glasgow Corporation also require tenders for creosoted poles, oak arms, insulators, ironwork, and ironwork used in telephone construction. Tenders by Wednesday, 16th inst.

Leeds Lighting committee invite tenders for two or three 630 kw. two-phase generators and one or two sets of surface condensing plant. An advertisement contains further particulars, and specifications, &c., may be obtained from the manager (Mr. H. Dickinson), 1, Whitehall-road, Leeds. Tenders to town clerk (Mr. W. J. Jeeves) not later than 10 a.m. of 28th inst.

Bradford Corporation invite tenders for the supply and delivery (for 12 months) of enclosed electric motors of 4½ H.P., 7 H.P., and 10 H.P. Specification, &c., may be obtained from the city electrical engineer (Mr. R. A. Chattock). Further particulars are given in an advertisement, and tenders must be sent to the town clerk (Mr. Frederick Stevens), Town Hall, Bradford on or before 24th inst.

Bradford Corporation also require tenders for the construction and delivery of two steam engines and two 1,000 kw. dynamos. Specifications may be obtained from the city electrical engineer (Mr. R. A. Chattock), and tenders must be delivered to the town clerk (Mr. Frederick Stevens), Town Hall, Bradford, on or before 24th inst. An advertisement gives further particulars.

Newcastle-upon-Tyne Tramways committee invite tenders for switchboards, underground feeders, and pumping apparatus. An advertisement contains additional particulars, and tenders for switchboards and feeders must be sent to the town clerk (Mr. Hill Motum) by 25th inst., and for the pumping apparatus by June 1. Specification and forms of tender can be obtained after 16th inst. from the consulting engineer, Mr. Chas. Hopkinson (Messrs. Hopkinson and Talbot), 26, Victoria-street, London, S.W.

Walthamstow District Council invite tenders for the supply and erection of arc lamp posts and accessories and glow lamps on posts and on existing gas standards in connection with their proposed system of electric lighting. Plans may be inspected and specifications obtained after 17th inst., at the offices of the consulting engineer (Mr. James Enright), 47, Victoria-street, London, S.W., and tenders must be delivered to the clerk (Mr. E. J. Gowen), Town Hall, Walthamstow, by 5 p.m. 29th inst. An advertisement gives additional particulars.

Walthamstow District Council invite tenders for fire alarms, wire, &c. An advertisement contains additional particulars, and forms of tender may be obtained from the surveyor (Mr. Edwin Morley). Tenders to the clerk (Mr. E. J. Gowen) before 5 p.m. of 25th inst.

Southampton Corporation invite tenders for the supply and erection of a water-tube boiler with steam and other pipes and sundry ironwork. Specification may be obtained (after 14th inst.) of the town clerk (Mr. R. R. Linthorne), and may be inspected (but not obtained) at the offices of the consulting engineers (Messrs. Kincaid, Waller and Manville), 29, St. George-street, Westminster. Tenders to Mr. Linthorne by 28th inst. See also advertisement.

Bridgwater Town Council invite tenders for the supply and erection of electricity generating plant as advertised in another column. Specifications, &c., may be obtained from the consulting

Digitized by Google

engineer (Mr. W. H. Trentham), 39, Victoria-street, Westminster, S.W. Tenders to town clerk (Mr. W. T. Baker), Town Hall, Bridgwater, before 3 p.m. on June 7th.

Crewe Town Council seek tenders for the supply and laying of about 25,000 yards of three-core cable for street lighting extensions, and the supply of upwards of 500 lamp holders and reflectors for adopting the existing lamp-posts for electric light. Specifications may be obtained from the engineers (Messrs. Hopkinson and Talbot), 26, Victoria-street, S.W., and tenders must be sent to Mr. Frederick Cooke, town clerk, Crewe, by May 26. See advertisement.

Glasgow Corporation invite tenders for the supply of two sets of switchboards and instruments for 4,000 amperes each. An advertisement gives further particulars, and the specification may be obtained from the chief engineer (Mr. W. A. Chamen), 75, Waterloo-street, Glasgow. Tenders with the town clerk (Sir J. D. Marwick) before 10 a.m. of June 12.

Dundee Town Council invite tenders for supply of copper bonds. Specifications, &c., may be obtained from the city electrical engineer (Mr. Walter H. Tittensor), Dudhope Crescent-road, and tenders must be lodged with the town clerk (Sir Thomas Thornton, LL.D.), City Chambers, Dundee, by 22nd inst. An advertisement contains additional particulars.

Edinburgh Corporation invite tenders for elevators and coal and ash conveyors for the McDonald-road electricity station. An advertisement gives further particulars, and specifications may be obtained from the resident engineer (Mr. F. A. Newington), Dewar-place. Specifications may be seen at, but not obtained from, the office of the consulting engineer (Prof. A. B. W. Kennedy), 17, Victoria-street, London, S.W. Tenders must be delivered to the town clerk (Mr. Thomas Hunter, W.S.) by 21st inst.

Worksop District Council require tenders for electricity generating plant. Tenders to clerk by 23rd inst.

The Guardians of *West Ham* Union invite tenders for the erection and maintenance for 12 months of electric lighting installation. Tenders to clerk, Union-road, Leytonstone, E., by May 16.

Heywood Corporation require tenders for electricity generating plant. Specifications, &c, from town clerk (Mr. J. H. Baldwick) and tenders by noon on May 14.

Corporation of *London* Streets committee invite tenders for the supply on hire of electrically-driven dust carts. Tenders to town clerk (Sir John B. Monckton), Guildhall, E.C., by June 1.

Paddington (London) Vestry invite tenders for carrying out certain proposed alterations to the existing electric lighting at the public baths. Tenders to vestry clerk (Mr. Frank Dethridge), Vestry Hall, Harrow-road, London, W., by May 14.

Burnley Corporation invite tenders for laying about 2,000yds. of cable. Tenders by May 14.

King's Lynn Corporation invite tenders for the supply of steam dynamos, boiler, switchboard and cables. Tenders by May 17.

Central Electric Supply Co. (Ltd.) invite tenders for electrical plant. Tenders to Mr. F. J. Walker, 19, Carnaby-st, London, W., by May 22.

Rhyl District Council invite tenders for the supply and erection of electricity generating plant. Tenders to Clerk by 2 p.m. of May 14.

Brighton Corporation invite tenders for incandescent lamps for 12 months from July 1 next. Tenders by June 11.

Tenders are invited for wiring the *Leeds* Central Fire Station. Tenders to town clerk by 28th inst.

The *Bengal Nagpur Railway Co.* (132, Gresham House, Old Broad-st., E.C.) require tenders for electric lighting plant. Tenders by May 10.

TENDERS RECEIVED AND ACCEPTED.

For the supply of electricity meters to the Brighton Corporation electricity works for one year from June 1, 1900, the following tenders were submitted (each) :—

Reason Manfacturing Co. (*accepted*)	£2	10	0	British Th.-Houston Co.	£4	5	0
General Electric Co.	5	5	0	Johnson & Phillips	4	0	0
S. Z. de Ferranti (Ltd.)	4	12	0	Chamberlain & Hookham	3	10	0
				British Electric Meter Co.	2	16	9

Messrs. Campbell and Isherwood's tender has been accepted by the Liverpool Select Vestry for wiring the Nurses' Homes at the Workhouse, Brownlow Hill.

The Sheffield Corporation have accepted the tender of Messrs. John Brown and Co. for the supply and erection of three marine-type boilers at the electric lighting station for £8,550. Bennis mechanical stokers are to be fitted to the boilers at £100 each.

The Birkenhead Corporation have accepted the following tenders : Tetlow Brothers, three Lancashire boilers and fuel economiser and mechanical stokers ; Siemens Brothers and Co., three steam dynamos ; Klein Engineering Co., independent condensing plant, re-cooling tower and two boiler feed pumps ; Electrical Power Storage Co., accumulators and booster ; Marshall, Fleming and Jack, a 12-ton overhead travelling crane.

APPOINTMENTS VACANT AND FILLED.

Accrington Corporation require the services of an electrical clerk of works to supervise, under the direction of their consulting engineer (Mr. J. N. Shoolbred), the laying of cables in the streets and the erection of electrical plant at the generating station, at a salary of £3 per week. Further particulars are given in an advertisement, and applications must be sent to Mr. A. H. Aitken, town clerk, Town Hall, Accrington, by noon of 18th inst.

The Hastings Corporation require an assistant electrical engineer. An advertisement contains further particulars, and applications must be sent to the borough electrical engineer (Mr. Leonard Andrews), Earl-street Works, Hastings.

The Johnson-Lundell Electric Traction Co. require an engineer and general manager and a secretary. Further particulars are set out in an advertisement, and applications should be addressed to the chairman (Mr. Leonard W. Holmes), 17, Soho-square, London, W.C.

Salford Electric Light committee require an electrical engineer, salary £400 per annum. Further particulars are set out in an advertisement, and applications (addressed to chairman of committee) must be forwarded to the town clerk (Mr. L. C. Evans) by noon of 21st inst.

The Aberystwith and Chiswick Electric Supply Corporation invite applications for the post of resident engineer at their Chiswick station, now building. Commencing salary £225 per annum. Applications to secretary. See advt.

An assistant lecturer and demonstrator in electrical engineering is required for the University College of North Wales, Bangor. Applications to the secretary and registrar (Mr. J. Lloyd, M.A.), not later than June 9. See advertisement.

The resident engineer of the Scarborough Electric Supply Co. has a vacancy for a pupil. See advt.

An advertisement invites applications for the post of managing engineer of a cable works on the Continent.

A switchboard attendant is required at the Hull Tramways' power station. Applications to City electrical engineer (Mr. A. S. Barnard), Dagger-lane, Hull. See advt.

Salford Corporation want a clerk of works for the electricity station at Pendleton. Applications to Mr. J. Holt, 6, St. Mary's Gate, Manchester, by 19th inst.

An installation inspector is wanted for the Manchester electrical department. Applications to chairman by 15th inst.

Mr. John Christie, of Glasgow, has been appointed resident electrical engineer and manager at the Brighton Corporation electricity works, under Mr. Arthur Wright, at a salary of £400 per annum, rising by annual increments of £25 to £500. There were 44 applicants for the position and these were reduced to four, viz. :— Mr. Christie (who asked for a salary of £450), Mr. R. H. Campion (of Blackburn, who asked £300), Mr. P. W. d'Alton (late of the London Electric Supply Corporation, who wanted £600), and Mr. A. A. Day (of Manchester, who required £400). After consultation with Mr. Wright it was decided to appoint Mr. Christie, the engagement being for five years, but determinable by the Corporation at one month's notice.

Since Mr. Turner's retirement from his position at Salford on Monday last, Mr. F. A. Wilkinson has been appointed borough electrical engineer (*pro tem.*). Mr. Wilkinson was previously the chief assistant engineer.

The Cardiff Lighting Committee have appointed Mr. W. H. Illingworth, of Halifax, mains superintendent at a salary of £150 per annum.

Mr. A. G. Hancock, late assistant electrical engineer at the Chatham, Rochester and District Electric Lighting Co.'s station has been appointed, out of 19 candidates, assistant engineer at Bray.

BANKRUPTCIES, LIQUIDATIONS, &c.

It has been resolved to wind up Howell's Anti-Inductive Telephone Syndicate (Ltd.) voluntarily, and Mr. D. F. Basden, 33, St. Swithin's-lane, E.C., has been appointed liquidator.

Claims against H. L. Howard (trading as Thompson, Howard and Co.), electrical and mechanical engineer, Wyvestow, Dragon-parade, Harrogate, and at York and Hull, must be in by 22nd inst. Mr. A. T. Wilkinson, O.R., 28, Stonegate, York, is trustee.

John Grant Macandrew, trading as the Waverley Electric Co, 117, George-street, Edinburgh, and Portobello, has executed a trust deed. The principal trade creditors include :—

Edison and Swan Co.	£140	7	7	Siemens Bros. and Co.	£19	4	4
Drake and Gorham	65	14	1	C. Joyner and Co.	15	15	1
Telegraph Manuf'ct'g Co.	51	3	2	General Electric Co.	15	9	0
D. F. Wishart and Co.	36	13	8	Mathew Buchan	12	10	0
John Hunt and Co.	25	15	0	J. W. Singer and Sons	12	9	2

The liabilities amount to £688. 0s. 2d., and the assets to £323. 10s. 5d. At a meeting of creditors on the 4th inst. it was proposed that debtor's father and other friends should pay on debtor's behalf a composition of 10s. Mr. Macandrew, sen., was allowed time to consider the suggestion.

Laing, Wharton and Down (Ltd.)—(In Liquidation).—In connection with the realisation of the assets of this company we understand that it will probably be some considerable time before the liquidator is able to make any proposition to the unsecured creditors. In the meantime it may be stated that these creditors are unlikely to receive payment of their debts in full.

Mannesmann Tube Co. (Ltd.)—(In Liquidation).—We learn that there are hopes of a small dividend being paid shortly to the unsecured creditors of this company. No distribution of assets can, however, take place until the debenture-holders' account has been settled, and the claims of the secured creditors, which are now being dealt with, are adjudicated upon.

Williamson and Joseph (Ltd.)—(In Liquidation).—In reply to our inquiries regarding the liquidation of Williamson and Joseph (Ltd.) we are informed that there is practically no prospect of any dividend being paid to the unsecured creditors in this matter. None of the assets of the company have so far come into the liquidator's hands, the receiver for the debenture holders being still in possession. This gentleman has up to the present, we understand, been unable to obtain an offer for the business sufficient to cover the amount of the debentures and interest.

Plant for Sale.—Messrs. Cornelius and Boulter, the Promenade, Cheltenham, announce in an advertisement the sale by auction on 22nd inst. at noon, of the contents (including electric lighting plant and machinery) of the Assembly Rooms, Cheltenham. Catalogues, &c., from the auctioneers.

The Tynemouth Corporation have a 30 H.P. Marshall steam engine and a belt-driven dynamo (175 amperes 65 volts) for sale. An advertisement gives additional information, and offers must be sent to the borough surveyor (Mr. John F. Smillie), Town Hall, North Shields, by noon of Tuesday the 22nd inst.

The Tunbridge Wells Corporation invite offers for their electricity works switchboard. Particulars may be obtained from the borough electrical engineer (Mr. Horace Boot). See Advt.

A 37-kw. Siemens dynamo is advertised for sale in another column. Applications to clerk of works, Eaton Hall, Chester.

"Monobloc" Accumulators.—Messrs. Drake and Gorham, sole agents in this country for the Monobloc Accumulator Syndicate, Ltd., forward a catalogue of these accumulators. The Monobloc is known on the Continent as the "New Julien," and references are given, in the list before us, to tramway systems abroad where this type of cell is in use. Tests and trials to which the cells have been subjected on the Continent give the capacity as 9 watt-hours and 5·22 ampere hours per lb. of electrode, and the efficiency is shown to be very high. Special plant has, we are informed, been installed at Bakewell, Derbyshire, for the manufacture of the cells on an extensive scale. The appearance of the Monobloc accumulator is familiar to our readers through the medium of our advertisement pages, and briefly it may be stated that the block of the positive material is composed of punched sheets of lead, built up from the bottom of the cell so as to form one homogeneous mass, which is crossed-tied at all points to give considerable mechanical strength. The holes punched in these horizontal sheets also form a casing and receptacle for the negative electrodes, which are in the form of vertical pencils. The tramway services at Ghent and Dunkirk have been conducted entirely with accumulator cars for more than a year, and the commercial results are said to compare favourably with the published figures for the trolley under similar conditions. At Ghent there are 36 cars in regular work and 11 reserve cars. The method of suspension of the cells under the car is such that the woodwork is not liable to damage by the acid.

"Constant" Arc Lamps.—Mr. G. Braulik, of 217 and 218, Upper Thames-street, London, E.C., forwards a new price list of continuous current "F" pattern arc lamps, manufactured by Messrs. Koerting and Mathieson. Mr. Braulik calls attention to the increased sales of these lamps, and states that some of the largest supply companies and corporations in the country are using them. There will shortly be ready a new price list of enclosed arcs for alternating and continuous current, also of double carbon and inverted arc lamps.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from May 2 to May 8, with the ports of destination:—

Africa—Cape Town, £43; Durban, £269. *Argentina*—Buenos Ayres, £88; Rosario, £52. *Australasia*—Adelaide, £76; Port Darwin, £8) (telegraph material); Sydney, £283; Wellington, £209. *Belgium*—Ostend, £36. *British Guiana*—Demerara, £41. *France*—Rouen, £105. *Germany*—Borkum, £21 200 (telegraph cable); Hamburg, £427 (including £400 telegraph material). *Gibraltar*—£130. *Holland*—Amsterdam, £85. *Hong Kong*, £52. *India*—Bombay, £685; Calcutta, £688 (including £317 telegraph material); Madras, £770. *Japan*—Kobe, £659; Nagasaki, £127; Yokohama, £3,235. *Mauritius*—£63 (telegraph material). *United States*—New York, £355. *Zanzibar*—£40. Total £30,798, against £8,484 in the corresponding week last year (May 3 to May 9).

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by MESSRS. J. C. CHAPMAN and Co, *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

April 4, 1900.

6,276. J. G. BEEVERS. Manchester. Improvements in shade or globe holders for electric lights.
6,296. W. BORCHERS. London. Improvements in electric furnaces.*
6,301. W. BEST. London. Improvements in or connected with means for electrically igniting miners' safety lamps
6,308. R. A. FESSENDEN. London. Improvements in incandescent lamps.*
6,312. H. A. COHN and E. GEISENBERGER. London. Improvements in and apparatus for the production of soda and chlorine by the electrolysis of chloride of sodium, the invention being also applicable for the production of potassium sodium, aluminium or other metals of the same class.
6,317. W. P. THOMPSON. London. Improved automatic interrupter for overhead conducting wires and the like. (E. Vittani, Italy.)

April 5, 1900.

6,348. H. D. WEBB. London. A new and improved insulation for electrical wires.
6,385. J. F. COOLEY. London. Improved methods of and apparatus for electrically separating the relatively volatile liquid component from the component of relatively fixed substances of composite fluids.*
6,405. W. H. SCOTT. London. Improvements in switches for use with electric motors.

April 6, 1900.

6,475. E. HARNETT. London. A self-contained electric incandescent lamp and method of charging same.
6,478. W. F. JONES. London. Improvements in electro-magnetic mechanism.*
6,479. P. RIBBE. London. Improved accumulator plate.*
6,488. SIEMENS BROS. AND CO. (LTD.). London. An improvement in apparatus for simultaneously actuating from one point the controlling switches of the several electrical motor cars of a tram. (Siemens and Halske, Actiengesellschaft, Germany.)*
6,496. J. SKOPEC and M. OREL. London. An improved automatic circuit breaker for use in connection with electric railways.

April 7, 1900.

6,499. R. A. LEHFELDT. London. An electric meter depending on the electrolysis of mercury.
6,526. A. MÜNKER. Berlin. Improvements in electric fire alarms.*
6,528. J. C. RICHARDSON and M. WHITWILL. London. Improvements in or relating to electrolytic apparatus.
6,530. J. C. RICHARDSON and M. WHITWILL. London. Improved capillary diaphragms for electrolytic apparatus.
6,533. F. M. BROWNE and R. ROWE. London. Photomatic-telegraphy by electricity for transmitting pictorial particulars so as to reproduce from distant places facsimiles of direct portraitures automatically and speedily.
6,540. M. STEIN and G. FREUND. London. Improvements in or relating to electric railways with underground conductors.*
6,548. H. B. WHITMORE. London. Improvements in brush holders for dynamo machines or electric motors.
6,564. R. GAERTNER. London. Improvements in reflectors for electric incandescence lamps.*

April 9, 1900.

6,615. W. R. EDWARDS. London. Improvements in terminals and binding screws for electric batteries and connections.
6,621. J. SAX AND CO. (LTD.). London. Improvements relating to electrical switches. (G. Busch, Germany.)
6,637. J. A. FLEMING and MARCONI'S WIRELESS TELEGRAPH CO. (LTD.). London. Improvements in relays.
6,642. C. F. MORRIS and W. HENLEY. London. Telephonic device for imitating the sound of guns.

April 10, 1900.

6,650. C. PETITJEAN. Coventry. Improvement in telephone switches.
6,652. A. D. HUNTER. London. Improvements in telephone transmitters.
6,671. E. FRANKE. London. Machine for filling accumulator plates with active materials.*
6,674. H. GOETZE. Dresden. Phonograph cylinders.
6,675. E. BAER. Dresden. Electrical key or stencel-board contact-apparatus for telegraphic communication.
6,681. E. DERVIN. London. Improvements in electric coherers.*
6,686. J. DEWAR and B. SHERMAN. London. Improved apparatus for forming a silence chamber for telephonic purposes and the like.
6,693. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in electric transformers. (W. S. Moody, United States.)*
6,701. O. C. STRECKER. London. Improvements in the process of electrolytically preparing metals or alloys for lithographic purposes.
6,703. T. BERGMANN. London. Improvements in electromagnetic light machines for regulating the sparking moment.*

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

1,434. BROWN. Electric telegraph apparatus.
4,360. VEDOVELLI and PRIESTLY. Apparatus for use in electric traction on the conduit system.
4,931. WISE (Crehore and Squier). Means for generating and impressing semi-cycles of electromotive force on electric circuits for telegraphic and other furnaces.
6,064. WISE. (Crehore and Squier.) Electric relays.
6,205. LOIR. Electric motor vehicles.
7,479. JUSTICE. (Priess Electric Storage Syndicate, Ltd.) Secondary batteries.
7,892. JUNGNER. Electrical batteries.
8,097. CHATTERLEY. Apparatus for regulating the arc in electric arc lamps.
8,240. PARTRIDGE and LONDON ELECTRIC SUPPLY CORPORATION (LTD.). Safety devices for use in connection with electrical distributing systems.
8,468. BOHLE, BOHLE and PHILLIPS. Arc lamps.
9,434. STOCKWELL. Electric arc lamps.
9,872. GRELET and VIVES. Phonographs.
10,238. DUBOIS and MUTUAL ELECTRIC TRUST (LTD.). Coin-operated mechanism specially applicable for electric and other meters.
10,839. SCHINDLER. Automatic electric cut-out devices for electric cooking apparatus.
11,325. BOCHET. Electric traction.
11,881. CRONEAU. Electrical apparatus for effecting rotation at a distance.
13,650. KENWAY. Bonds for electric tramways and railways.
25,403. MATHEWS. Electric low-water alarm for steam generators.
25,768. ROWNTREE. Electric lifts or elevators.

COMPANIES' MEETINGS AND REPORTS.

Western Telegraph Co. (Ltd.).

The fifty-third ordinary general meeting of the shareholders was held on Wednesday, at Winchester House, London, E.C., under the presidency of Mr. W. S. ANDREWS.

The SECRETARY (Mr. E. Steer Hodson) read the notice convening the meeting,

The CHAIRMAN said: What I have to say to-day does not amount to very much. So far, however, as it goes, I think you will agree that it is particularly satisfactory, because it shows the continued existence of the annual augmentation in our receipts which all shareholders, equally with all directors, like to be able to perceive in the figures. The income for the half-year ended Dec. 31, 1899, including dividends from the Western and Brazilian Telegraph Co. and other telegraph companies, amounted to £139,596. For the previous half-year the total reached was £119,360, so that you see an increase is shown upon the figures of the last half-year of £20,236. This improvement results from an increase in message receipts, which are, as a fact, rather larger, the amount thus netted being £22,381. That is on the right side, but, as you know, this company receives from other companies certain dividends, and sometimes the periods at which those dividends are paid are not identical in the different years, so that there may be a little variation. This does not affect the total eventually, of course, because they average one another, but, as a fact, there was in this year a decrease of £2,145 from the circumstance I have stated. Then, the increase in the traffic receipts shows, on being analysed, that we got most of the increase from the east coast of South America; but there has been an increase in the receipts from the west coast of South America and from the west coast of Africa, with a slight decrease in the traffic with South Africa. The principal item is the large increase in the receipts from the east coast of South America. Turning to the expenditure side of the accounts, we find that the total expenditure for the half-year was £25,596, while that for the previous half-year was £21,999. There is therefore an increase in the expenditure in the past half-year of £3,597. There was an increase in the London expenses of only £209, but in other expenses the increase was £3,524, less a decrease in working expenses at the stations of £136, leaving the net increase at £3,597. As showing that we do not increase our expenses needlessly, I may say that practically the increase which I have mentioned in the expenditure this time is nearly all made up by the cost of repairs of cables, which item exceeded by £3,100 the amount spent under the same heading in the preceding six months. As you know, that is an item which is not within our control. The breaking of your cables results from natural causes, and all that we can do when it happens is to repair the cables as quickly as we possibly can, so that the break may not interfere with your trade. There may be more expenses on this account as the cables grow older, but that is an unknown quantity, and it does not do to dwell upon it. After payment of £3,200 for debenture interest and sinking fund, and providing for the payment of income-tax, there is a credit balance on the half-year's business of £109,284. To this has to be added £5,062 the balance brought forward from June, making together £114,346, from which £177, further expenses in connection with the closer working union of the companies, and two interim dividends for the September and December quarters, amounting to £62,379, have been paid, and this leaves a balance of £51,791. Then we have transferred £45,000 to the reserve fund, and after that operation a balance is left of £6,791 to be carried forward. That seems to me to be a pretty satisfactory state of affairs. Then it is an agreeable thing to know that since our last meeting the remaining interests of shareholders in the Western and Brazilian Telegraph Co. have been acquired, so that we may now look on it that we are not only under one roof, but that we are one institution; and henceforward you will hear not of the Western and Brazilian Telegraph Co., because it will very soon disappear from this sublunary sphere altogether, and your attention will be confined to the Western Telegraph Co.—the new name of the company. As far as we can gather (it never does, of course, to prophesy) we hear very good accounts of what is likely to be the condition of the United States of Brazil for some longish period to come. The country seems, as far as we can gather, to have taken a turn. It has passed through the darkest period, and seems to be emerging into the light. What will be the intensity of the light, of course, we cannot prognosticate, but all circumstances seem to run pretty much together—rise in exchange, increase in general business, increase in our business, and so on—as pointing to a satisfactory future. We therefore seem to have passed the most gloomy period, but I do not think after all that our gloom, even under those circumstances, has been extreme. In making these arrangements for the companies coming together certain questions had to be considered, and one of them was the question of duplicating the existing cable in the interests of the Government; and you may remember that we told you that that agreed very much with our own desires. We have suffered a good deal from breakages of one of the cables, and it has cost us much for repairs, and interfered more or less with the traffic. We are now proposing to lay—in fact, we have been laying part of it—a new cable of an exceedingly excellent type, which is to give us a high rate of speed right away from Para to the Plate. We are very pleased to see that the laying of this new cable appears to coincide with what we are led to believe will be the almost immediate future of Brazilian trade and commerce, and therefore we have taken a step in time, which will probably result in a very satisfactory state of receipts, and so on. We have also had to increase the accommodation at certain stations in connection with our line, which we believe will also give us a certain increase, though not a material increase, of business. Well, these things are not to be done for nothing—they will cost money; but to the extent by which you deplete your reserve fund—by which extent you will deplete yourselves of interest now coming in—you will have something that will turn out better—namely, this new additional direct line, and the great encouragement and growth we expect in the traffic that will ensue from the laying of it; and we look on that substitution of good working plant for the reserve as a more advantageous investment. The steamship "Buccaneer" has had to be chartered because we have been obliged to send home the "Norseman" for repairs. She will be overhauled thoroughly, and we may find means of effecting certain economies in her working; at all events, we shall try to do so. The next matter I have to draw your attention to is the question of the superannuation fund and the pension fund. It works very well, but at the same time we have felt that there is an inconvenience in it in that the clerks are supposed always to be continued in the service until the age of 60. Now, 60 for a telegraph clerk is rather an advanced period of life, and we want therefore to make an alteration in the pension fund to the effect that we make the pension payable at the age of 55 instead of 60. You must not of course gather from that that we propose to remove these gentlemen from our staff at the age of 55. We should not do that unless we find the services of any particular individual or the state of his health after long service in the tropics such that it would make it advantageous for the company to pay the pension instead of continuing the man in the performance of his active duties. We do not think that this will be very costly to the company. It is true that a loss has been talked of, and the resolution is obliged to take that form, but if there should be any loss, it is to be made up. As a fact, no loss in the superannuation fund is anticipated, although it is necessary to take the resolution in that way; and as respect any deficiency in the pension fund, the sum required is estimated by the actuaries at less than a total of £3,000, spread over 20 years. That is not a very desperate thing. Supposing the whole of the staff of the Western and Brazilian Co. to join in these measures—and, of course, whatever measures there are for the benefit of the staff must be extended to all, supposing them all to join the fund, and the adhesion of all the new officials—that would amount in all to about £1,200 a year. I do not think there is anything else that I need draw your attention to, and therefore I will conclude by moving—

"That the report of the directors and the accounts to Dec. 31, 1899, now submitted, be approved and adopted."

Sir A. J. LEPPOC CAPPEL, K.C.I.E., seconded the motion, which was carried unanimously.

The CHAIRMAN then proposed a resolution authorising the directors to make such contribution as were necessary to make the staff superannuation and pension funds operative at 55 instead of 60 years of age, and to amend the indentures of these funds accordingly.

Mr. D. H. GOODSALL seconded the motion, which was carried unanimously.

Mr. ENNIS afterwards proposed a vote of thanks to the chairman, directors, and officers, whose services he warmly recognised.

Major COTTON seconded the motion, and referred especially to the admirable manner in which the amalgamation had been carried out between the Western and Brazilian and the Brazilian Submarine Companies—a measure which, he said, would prove greatly to the interests of the shareholders.

The resolution was carried unanimously, and was briefly acknowledged by the chairman, and the proceedings terminated.

Cuba Submarine Telegraph Co. (Ltd.).

The fifty-seventh ordinary general meeting of this company was held on Wednesday, at the offices, 53, Old Broad-street, London, E.C., Mr. CHARLES W. PARISH presiding.

The SECRETARY (Mr. James Scott) read the notice calling the meeting.

The CHAIRMAN said: The revenue account is by no means so encouraging as we have been accustomed to. You may remember that it was in 1895 that the revolution in Cuba took a serious form; up to that time we were in full enjoyment of advantageous rates, and although these were reduced in 1898, on account of the competition from the New York-Hayti cable and the Bermuda-Jamaica cable, owned by the Direct West India Co., the loss was more than compensated for by the increased business brought us by the revolution and the Spanish-American war—directly I may say, by the heavy Government work, and indirectly from the land lines being destroyed by the Cuban rebels, which naturally caused a considerable increase of local business to be sent over our cables. As you are aware, I have at our late meetings urged you to be prepared for reduced receipts, and we have not hesitated to strengthen our reserve fund as much as possible during the exceptionally good years that we have enjoyed, that we might be the better prepared to face the lean years to follow when peace was restored. The actual traffic receipts for the half-year ending Dec. 31st amount to £12,008, as compared with £25,740 during the corresponding half-year of 1898, a falling off of more than 50 per cent., which as stated in the report is due principally to the lower rates at which we are working, and to the competition of the land lines which have now been restored. I may also point out that during the last half of 1898 we were still dealing with some extra business caused from the war. The second item of the revenue account is the sum of £5,316 which we have received on outstanding accounts, and is part of the amount I explained to you at our last meeting was received at Madrid from the Spanish Government, against the balance of certain accounts for Government messages sent during the war, and which had not been settled by the Spanish officials before leaving the island, and were treated as outstandings in our accounts. The third item of our revenue comes from interest on investments and deposits, and amounts to £2,181, which is a larger sum than usual, for we have had the benefit of a high rate of interest on a large cash balance. Taking all sources of income together, we have received £19,512, against £27,483 in the corresponding period of 1898. Our expenses in 1899 amounted to £6,192, against £7,585 in 1898, a reduction of £1,393, which is chiefly accounted for by £207 under salaries and wages, £330 maintenance of lines, £133 printing and stationery, and £515 depreciation on stores and cable in stock. We have carried £4,937 to reserve fund, which brings up this account to £130,000, and after paying our preference dividend we are able to propose a dividend at the rate of 6 per cent. per annum, which after all is not an unsatisfactory result. This brings me to the sixth paragraph of our report, which refers to the state of our cables. The break in the Cape Cruz-Manzanillo cable was repaired without difficulty, but I regret to tell you that the section between Cienfuegos and Cape Cruz, which was laid in 1831, proved so extremely weak that it was impossible to lift and repair it. This was the cable which was laid on the deferred payment system; it was not originally made for our company but it has done us good service. We have now one cable working direct from Cienfuegos to Santiago, and this line is practically duplicated by the coast cables. You will have learnt from the report that Mr. Keith and Mr. Scott have lately visited America in the interests of our company, and I am very glad they did so, for I believe that considerable benefit will result from their journey. It may be a convenience if I refer to the present position we are in towards the United States Government. There are three points we are anxious to have settled. In the first place, we would like the American Government to recognise our concessions, which they have not yet done; secondly, we desire payment of our subsidy of £2,000 per annum, due under our 1895 concession for the coast cables; and thirdly, there is the claim of £8,174 for the cost of repairing the damage done to our property during the Spanish American war. You are aware that we turned to the Foreign Office who have been most helpful, and negotiations are now being carried on by Her Majesty's Ambassador in Washington with the United States Government. As a result of these negotiations we have lately been informed by Lord Salisbury that the question of our concessionary rights and the arrears of the subsidy have been referred to the United States Secretary of War, under whose department the matter is receiving attention; and as regards the claim for £8,174 for damage done, President McKinley has asked the Senate and House of Representatives to reimburse to our company the expenses we have incurred. You may have noticed in the newspapers a reference to the message that the President sent, but we have not yet heard if this message has come up for discussion; at any rate, I hope you will gather from what I have said that your interests are being well looked after. We received the subsidy from the Spanish Government up to the end of 1898, but so far we have received no payment since, which is a great hardship, for we would never have laid the coast cables without the promised subsidy. Mr. Keith and Mr. Scott had the opportunity when in New York of discussing with the International Co. our mutual interests, which was very advantageous. Our rates are very low, but we hope as the state of the island improves we may have the benefit of some increase in business, though, on the other hand, trade is bad in the West Indies, and there seems no expansion of traffic from that source. As far as our receipts have gone for this year they appear much the same as those for the six months we are now dealing with. I now move the adoption of the report and accounts.

Mr. GEORGE KEITH: I beg to second that.

Mr. PRICE: What position will the company in future be in as against the overland competition? Will your concession, if recognised by the United States Government, give you a monopoly of the communication between the various points where you touch, or will you have to face severe overland competition?

The CHAIRMAN: I think we must always be prepared to meet competition. The land lines are now practically being worked under the charge of American officials and naturally they will send a great many messages over those lines. We have certain rights under our concessions, and though, perhaps, they should give us more traffic than they do, it is an exceedingly complicated matter, but I may tell you that we are watching it as closely as possible.

Mr. PRICE: But will not the system of overland lines virtually kill the business of the company?

The CHAIRMAN: There have always been overland wires, only from one cause or another they have not been very successfully worked.

Mr. PRICE: I know Cuba—that part of it—a little, and I am aware that in the past there has not been very much competition overland, but with the Americans working them I fear things will be different.

The CHAIRMAN: That is what we refer to in the report.

The resolution was then unanimously carried.

A resolution approving the payments on dividend account set out in the report was unanimously approved, and a cordial vote of thanks to the chairman and directors terminated the proceedings.

West Coast of America Telegraph Co. (Ltd.).

The third ordinary general meeting was held on Tuesday, at the offices, Winchester House, London, E.C., under the presidency of Mr. J. DENISON-PENDER.

The SECRETARY (Mr. Fred. L. Robinson) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, you will see by the report and accounts that the receipts for the year ended Dec. 31 last were £28,347, as compared with £25,080 in 1898, thus showing an increase of £3,267. This satisfactory result has been chiefly derived, of course, from an increase of traffic, which has come from some revival of trade on the coast, and the exchange, which has gone up from 12½d., about the average of 1898, to 16d., which has been the average of 1899, or nearly so. Having regard to the increase in receipts, you will naturally turn to the expenditure to see if there has been an increase there, and I am sorry to say that there has been, although I think I can show you that it has been impossible to keep the expenditure down further. The expenses in 1899 were £21,065, as against £18,840 in 1898. Thus the increase in the expenditure has been £2,224. The cause of this increase has been chiefly the repairs of cable, and of course where you have repairs you have the cost of the new cable you put in, which is a very material item. Also with respect to the ship, we, as you know, get a rebate on every week that she is lying in harbour doing nothing. During the 12 months under consideration the ship had been out more than usual, and therefore the cost of insurance has been considerably greater, to say nothing of the increased cost of coal, of which everyone is aware. The sections under repair have been for the 12 months from Serena to Valparaiso, which was repaired in March and again in August. The cause of the interruption there was found to be the bad ground upon which the cable was laid, it being rocky. The line has been moved further seawards, and I think we have better ground there now, and are therefore not so likely to have interruptions. Another repair has been in the Caldera-Serena cable, which was repaired in the beginning of March, and at the end of March again. That latter repair was caused by a landslip, which tautened out the cable and put a fault into it. Another repair has been to the shore end at Antofagasta, where the shore end has been renewed. I think I have mentioned at previous meetings that with respect to expenditure, especially in a company such as this, it entirely depends on the cable repairs; and if we are fortunate enough one year to have the expenditure low, we must not count very much on that, because the next year may bring, as the last year brought, a considerable increase in the item. With respect to the balance that we have of £7,282 you will see that that has been dealt with by the payment of the interest on the debentures and the income bonds. These bonds, you will remember, were issued at the time of the reconstruction of this company. They were taken by our good friends, the Brazilian Co., and some were also taken by the Construction Co., but the interest on them is not cumulative. For two years we paid nothing on them, but this year I am glad to say that we have been able to pay the 4 per cent. out of profits. That is certainly a move in the right direction. The only important event that has taken place in connection with this company this year has been the closing of one of our offices. We have taken the cable out at Caldera, and have closed that office. It has lately never paid its expenses, and therefore it was for the benefit of the company that the expenditure should be reduced there. Meanwhile the public will not suffer in the least, because there is a Government land line, and the traffic will be handed to the Government. The messages which are to be transmitted to Europe or other parts of the world will come on to our line at one of the other stations. I do not think I have anything more to say to you on this occasion. If the political situation in South America remains quiet, we have every reason to hope that even the present figures, which are distinctly satisfactory compared with those of the previous year, may be more satisfactory in the future. I may mention that last year we had a certain accession of traffic owing to the fact that the cable of our neighbours, the Central and South American Co., was broken down. This year that cable has not been broken down, but nevertheless our traffics so far

Digitized by Google

show an increase on those of last year. I now move the adoption of the report and accounts.

Sir ALBERT J. LEPPOC CAPPEL, K.C.I.E., seconded the motion, which was carried unanimously.

A vote of thanks to the chairman terminated the proceedings.

Submarine Cables Trust.

The twenty-ninth ordinary annual meeting of the certificate holders of this Trust was held on Tuesday at the offices, Winchester House, London, E.C., under the presidency of the Most Hon. the Marquis of TWEEDDALE.

The SECRETARY (Mr. Sidney Collett) having read the notice calling the meeting,

The CHAIRMAN said: I have now to ask your approval of the report and accounts, which I presume you will take as read. The income for the past year amounted to £24,789, or an increase over that of 1898 of £3,333. The principal cause of this apparent increase in the income of the Trust is that we have received, and brought into the credit of our revenue account, a full year's dividend and bonus on the shares of the Eastern Extension Telegraph Co., amounting to £9,294, whereas last year only three full quarters, and the balance of the December quarter, 1897, were carried to the credit of revenue, making a total of £5,994, or a difference of £3,300. In previous years it was customary to bring into our revenue account the December quarter's dividend and bonus for the year in respect of our holding in the Eastern Extension Co., which was sometimes paid a few days after the date of making up our accounts; but we are now able to leave this dividend out of the revenue account until it has actually been received by us. There are one or two other differences which make it difficult to properly compare the amount of the dividends received during the current year with the previous year, owing to the dates of the receipt of dividends being somewhat variable, more particularly in the case of the American investments; but these differences are all fully explained by notes under the schedule of stocks and shares held by the Trust and income received therefrom, which will be found on page 2 of last year's accounts and page 6 of the present year's accounts. It will be seen on reference to the revenue account that after deducting the expenses of the Trust, there is an available balance of £23,601, which has been sufficient to pay two coupons of £3 each, due on October 15, 1899, and April 15, 1900, and leave a balance of £3,315. In accordance with the terms of the Trust deed, the surplus funds of the Trust are to be used in the redemption of certificates, either by purchase in the open market, provided that the price paid for each certificate be less than £120, or secondly, by tender from the certificate holders for the redemption of certificates held by them, provided that no tender shall be accepted at a higher price than £120; and, failing those two methods, by drawings at £120. Inasmuch as the price of the certificates was quoted above £120 ex div., the trustees decided to draw 27 certificates, which was done on Friday, April 27, this year. In paragraph 5 of the report will be found full particulars of the changes which have been made during the year in the investments of the Trust. They are very few, and practically consist of the sale of some Anglo-American stock in order to enable us to take advantage of an offer made by the Commercial Cable Co. of our proportion of a new issue of their shares at par. This being a very profitable transaction for the Trust, we had no hesitation in agreeing to take them. I now move the adoption of the report and accounts.

Mr. J. DENISON-PENDER seconded the resolution, which was carried unanimously.

The CHAIRMAN: I have now to propose—

"*That the unanimous resolution of the Trustees to invest the produce of the sale of £1,200 Anglo-American Telegraph Co.'s preferred stock in the purchase of 66 shares of $100 each of the Commercial Cable Co., and £15 ordinary stock of the Eastern Telegraph Co. (Ltd.), be and the same is hereby confirmed.*"

Sir A. J. LEPPOC CAPPEL seconded the motion, which was carried unanimously.

Messrs. Deloitte, Dever, Griffiths and Co. and Messrs. Gane, Jackson, Jefferies and Wells were afterwards elected auditors of the Trust for the current year.

The CHAIRMAN, in acknowledging a vote of thanks, observed that he thought the Trust was now getting into a very satisfactory condition.

The proceedings then terminated.

London Platino-Brazilian Telegraph Co. (Ltd.).

The twenty-second ordinary general meeting of this company was held on Tuesday, Mr. W. S. ANDREWS presiding.

The SECRETARY (Mr. E. Steer Hodson) having read the notice calling the meeting,

The CHAIRMAN stated that the income for 1899 was £29,643, or £6,645 less than that for 1898. There was, however, really an increase in the cable receipts, amounting to about £660, but there was a decrease in land line traffic receipts of £7,328. This arose from an accidental circumstance—the payment in 1898 by the Government of £5,000 odd for night service performed during the disturbances. The expenses for 1899 were £6,832, a net decrease of £1,480 compared with 1898, owing to savings which had been effected by the closer working union of the company with the Western Telegraph Co. The profit in 1899 was £22,531, a decrease of £5,052 on 1898. Including £2,859 brought forward from 1898, the amount available at Dec. 31 last, after paying the usual debenture interest, was £19,390. An interim dividend of 4s. 6d. a share was paid in respect of the June half of 1899, and the directors now proposed a further dividend of 2s. 6d. a share, making the same distribution as for 1898. This would leave £6,249, from which they had made a transfer to reserve of £5,000, leaving £1,249 to be carried forward. He concluded by moving the adoption of the report and the payment of the dividend recommended, making 3½ per cent. for the year.

Mr. J. DENISON-PENDER seconded the motion, which was carried unanimously.

Messrs. Deloitte, Dever, Griffiths, and Co. were re-elected auditors, and a vote of thanks to the chairman closed the meeting.

Hampstead Electric Supply Co. (Ltd.).

The annual meeting of this company was held on Monday, Mr. E. T. READ, F.R.G.S., presiding.

The CHAIRMAN, in moving the adoption of the report, first dealt with the accounts for the 13 months ended Dec. 31st last. He pointed out that, in addition to the £165,000 paid for the assets of the Hampstead Battery Co., there had been expended upwards of £16,000 for further plant and other property. This might appear rather a large sum, but it gave him, personally, much satisfaction, as it indicated that their business was a progressive, and not a stagnant one. The expenditure by the company on motor cars, experiments, &c., had been £729, of which one-fifth had been written off. One of the future outlets for their day current they expected to be the supply of power for motor cars, and that would be a profitable source of revenue. Up to the present, however, the accumulators used for motor cars were very heavy, and did not satisfy the requirements in the case of light vehicles. The London Electric Cab Co. had had to suspend running their cabs temporarily, as they found that the accumulators, though so heavy, would not store the requisite amount of electric energy to enable the vehicles to be run with satisfaction. That difficulty was now being overcome. The electric motor traffic industry was in its infancy, and he had not the slightest doubt that within a short time accumulators would be devised which would do all that was wanted. He was happy to say that, so far as the electric light portion of the company's business was concerned, the capital expenditure was now practically stopped for a certain period. Speaking roughly, there had been added to their customers' roll some 200 houses during the period under review, and besides that, at the end of 1899, they connected the large stores in the Finchley-road, belonging to John Barnes and Co. (Ltd.). Current was supplied to those stores only at Easter, after the close of the period covered by the accounts. The number of lamps connected at those stores were equivalent to 44,000 c.p.; and, in addition, the lifts in the building were being operated electrically. The company had in hand contracts for connecting 500 houses further, and many other estates were being developed in the district which would, no doubt, bring to the company more orders for current. In not a single instance had the company's light failed, except in one small case where the wires were for an hour or two interrupted by the action of railway employés. That was a thing which he thought few electric light companies could say. The profit on the electric light department for the 13 months was £5,000 odd, and it would have been larger but for the great rise in the price of coal. The directors had been testing certain mechanical contrivances by which, if coal was maintained at its present high price, it would be possible to burn an inferior class of coal without giving off a tremendous lot of smoke in the neighbourhood. So far as they had gone, the experiments had resulted admirably. The profits from Taylor and Lown's department had been disappointing, but this was due to trade reasons which it would not be advisable to enter into. Messrs. W. P. J. Fawcus, E. J. Cave, and D. H. Evans had resigned from the board because they were not able to give the necessary time to the affairs of the company. He was convinced that they had a sound and progressive business capable of making a profit of anything between £10,000 and £15,000 per annum. It was an exceptional thing for an electric light company to pay a dividend until it had been established several years. This company had already distributed something by way of dividend although they had had to pass the dividend for the half-year ended Dec. 31st last. The business was increasing so fast that the company had not enough money to properly deal with it, but the directors were taking steps to provide for the necessity.

The motion having been seconded, Mr. PARKER expressed himself as disappointed with the report, and remarked that the prospectus promised the shareholders a profit of £18,000 per annum. It seemed to him that the company was going from bad to worse. The chairman had held out the prospect of further capital being raised, with the further deferring of the hopes of the shareholders with regard to a dividend.

The CHAIRMAN said that he could not agree with Mr. Parker. He considered the report a satisfactory one.

Mr. PRESTON asked if, in view of the large diminution in the profits foreshadowed in the prospectus, the board contemplated taking any steps to obtain the repayment by the vendors of a portion of the purchase money.

The CHAIRMAN replied in the negative, and added that he considered it would be time and money thrown away to attempt anything of the sort.

Mr. PRESTON moved, as an amendment, the appointment of a committee of shareholders to investigate the affairs of the company.

Mr. FUCHSBALG seconded the amendment, which, on a show of hands, was declared negatived.

The original motion was then carried, with about half-a-dozen dissentients.

New General Traction Co. (Ltd.).

The directors' report states that the gross profits for the past year were £76,299. 17s. 5d., after deducting £6,116. 10s. 6d. for general expenses, salaries, &c., chargeable against revenue. With £6,212. 4s. 10d. from last year, the total was £82,512. 2s. 3d. The further £100,000 6 per cent. preference capital was placed in June last. After deducting the dividend of 6 per cent. on the outstanding preference capital for the past year (£13,487. 13s. 4d.), a balance of £68,742. 19s. 6d. remains, which the directors propose shall be dealt with by transferring £10,769. 5s. 8d. to reserve, £942. 18s 8d. to meet difference of present market value of consols purchased and lodged as caution money, and the purchase price

Digitized by Google

(£20,000) to general reserve, and to carry forward the balance of £37,030. 15s. 2d.

The directors consider the result of the year's work satisfactory. During the year considerable progress has been made in the company's operations. The system of electric tramways at Coventry was completed and opened for traffic in January last, and is now in regular operation. The work at Norwich is nearly finished, and it is expected that the system of some 20 miles will be opened and working during the next few weeks. Great progress has also been made with the work of this company's lines in the vicinity of Philadelphia. The system there amounts to about 20 miles, 13 miles of which will shortly be opened. During the year a considerable amount of new business has been submitted to the company, but the only new business concluded has been an extension of the lines at Philadelphia, and an arrangement come to with the town of Airdrie. An Act for the construction of a short line of tramway in the latter district is now before Parliament. Resolutions to carry out certain alterations in the articles of association will be submitted to the meeting for approval.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Jan. 25, 1900). Price of silver 27½d. per oz. (May 10). Consols (2¾ per cent.) 100—100¼ for money, 100$\frac{7}{16}$—100$\frac{7}{16}$ for account; 2½ per cent. 97½—98 (May 10). Stock Exchange Settling Day: Consols, May 4; Stocks and Shares Continuation Days, May 14 and 29; Ticket Days, May 15 and 30; Pay Days, May 16 and 31; Mining Share Carry-over Days, May 11 and 28.

EDWARDS AIR PUMP SYNDICATE (LTD.)—At the annual meeting on Wednesday the chairman (Mr. C. W. Milne) said that the income from royalties was £3,219, compared with £1,768 in the previous 15 months. The progress made was entirely satisfactory. The syndicate had popularized the pump among electrical engineers and engineers for large ironworks, &c, and the revenue from that source had considerably increased. He was sorry that up to the present they had not disposed of any of their foreign patents. He believed that the more likely source of revenue from America and European countries would be by giving a licence for the use of the foreign patents to first-class engineering firms in those countries. The report was adopted and Mr. Edwards then explained that his reason for resigning his seat at the board was that he felt he could hardly do the syndicate justice. There were seven foreign patents on which no royalty had been received during last year. He admitted that the directors had been handicapped by not having funds to work these patents.

NOTES.

ELECTRICAL schemes still continue to occupy a large share of the attention of the committees of both Houses of Parliament. During the past week seven electrical bills have been brought before committees of the House of Lords, while committees of the House of Commons have had before them a similar number, not to mention official bills for the confirmation of provisional orders. Of these 14 bills no fewer than 10 relate to electric traction on railways or tramways, three to electric lighting schemes, and one—the Tyneside bill—to an extensive power scheme, already described in our columns. Doubtless our readers will learn with surprise that during another entire week the Tyneside bill has danced its long *pas de deux* with the Durham bill before Sir JAMES KITSON'S all-too-patient committee. Local municipal opposition, Ossa piled on Pelion, accounts for the greater part of this extravagant consumption of precious time; but it is clear that the partisans of local municipalisation are hugely overdoing their resistance. Unfortunately, however, all this iteration and reiteration *ad nauseam* of the arguments of the opponents tend to push the conclusion of the work of the Select Committee dangerously near to the summer vacation, and may seriously retard, even though failing to overthrow, these power schemes.

IN the room adjoining that in which Sir J. KITSON'S Select Committee is sitting, the bill providing for the electric express railway between Liverpool and Manchester has been occupying throughout the week the attention of another Select Committee, presided over by Sir J. KENNAWAY. Owing to the novel character of this proposed railway, technical matters have had to be sifted very thoroughly in the evidence and cross-examinations. Among these the questions as to limiting speed and the provision of adequate brake power were, perhaps, those of greatest interest to our readers. Expert evidence was given as to the facility with which a speed of 110 miles an hour could be attained and maintained by electric traction on the mono-rail system, Sir WILLIAM PREECE, Dr. EDWARD HOPKINSON, Mr. S. B. COTTRELL, and Mr. H. F. PARSHALL testifying to this. A more serious problem, however, was presented by the braking requirements at such a high speed, though we are sure that it is one for which there is happily a quite satisfactory solution. At 110 miles an hour a train weighing 45 tons would possess kinetic energy amounting to 41 million foot pounds. To dissipate this energy at the brakes would develop so much heat that a dangerously high temperature might be developed, were not special provision to be made to get rid of the heat quickly.

THE ultimate possible speed on a railway, however, is not so much a matter of engineering as of finance. It is the pace that kills—the capitalist, not the passenger. There is a limit, in fact, to the price people would be willing to pay for travelling fast, or the price which a benevolent Government would allow express railway companies to charge them. On the other hand, a railway costs more both in capital outlay and in annual expenditure, in proportion to the speed. Few people nowadays resemble the Scotchman who was delighted with a 24 hours' journey from Edinburgh to London, by way of compensation for the enormous draft upon his purse; but the number of people must be still fewer who would pay double fare for double speed, as a general practice. Accordingly, express railways like that now proposed must have their speed limited to such a figure that the permissible fare will attract a sufficiently remunerative traffic. As time goes on, pressure of business will doubtless raise this limit even to far above 110 miles an hour.

IN a strongly-worded article, our contemporary *L'Industrie Electrique* warns intending visitors to the Paris Exhibition that all the installations and exhibits in the electrical section will not be completed before June 15; and this article having been written before the fire in the Château d'Eau and the destruction of an important part of the switching appliances, it appears not improbable that the date of actual completion will be even later. At the opening of the Exhibition the state-

Digitized by Google

ment on all sides that the electrical generating plant would not be in operation for a fortnight was treated with scepticism, for it appeared incredible than an exhibition of this character should be opened before proper provision had been made for lighting it. These forebodings, however, fell far short of the mark, and the date given was first shifted from the beginning to the middle of May; and even now what electric lighting and power supply is available is being delivered to a large extent through temporary connections, so that the forecast of our contemporary is by no means improbable. Fault is also found with the architectural arrangement of the Palais de l'Electricité, for some of the important exhibits have had to be placed in low-roofed parts of the building which some writers have sarcastically termed *oubliettes*. Our contemporary, however, seeks to console exhibitors in these parts by suggesting that during the hot weather visitors will be attracted thither by the coolness and shade!

WHILE we in this country have been discussing the storage battery problems to which Mr. WADE recently directed our attention, Dr. PETERS has contributed an article to the *Centralblatt für Accumulatoren und Elementenkunde* giving the results of some experiments he has been making with the object of ascertaining, if possible, the cause of the softening of the positive plates which occurs in the cells of the pasted type after they have been in use for a long time. We hope that the abstract of his article, which appears in another column, may lead to that exchange of views and experience which Dr. PETERS desires. German electricians have gone into the question of the storage of electrical energy by chemical means with their accustomed thoroughness, and with the advantage of a more sound training in chemistry than is usually possessed by electrical engineers in this country; and if we do not wish to be outstripped in the race we must follow their example and make a systematic examination of the products formed in the storage cell.

OUR esteemed contemporary the *Journal of Gas Lighting* has been greatly excited, in its last two issues, over what it deems an unfair comparison between gas and electric meters, recently made by a German electrical journal. Our contemporary evidently believes the comparison to have originated with ourselves, overlooking the fact that it appeared in a brief abstract we published of an article in the *Elektrotechnische Zeitschrift* for April 5. The article gave some interesting statistics collected by the Physikalisch-Technische Reichsanstalt, which we summarised, as to the use of electricity meters in Germany. In the course of the article statements were made, of which the following is a translation:—

> It is to be noticed, in addition, that in gas meters also great accuracy cannot be attained. Owing to the influence of the pressure of the gas, temperature, and the chemical composition of the gas, which primarily determine the heat energy conveyed by the gas, the gas meter is burdened with so many sources of error as a work-measurer that, as compared with it, the electricity meter in its present form must be designated as quite an accurate apparatus, even at small loads.

OUR gas contemporary challenged *us* to prove this assertion, which we gave in a somewhat condensed form. It declared that it did "not mean to let [its] contemporary off from this task." And then, because we were too occupied last week with far graver matters to take up this ridiculous challenge at once, it has issued the following amazing proclamation:—

> The challenge we addressed last week to *The Electrician* to make good its astounding claim for superior accuracy of electricity meters to gas meters has not been taken up in the current issue of our contemporary. We have scanned its columns carefully without finding any notice of our imputation upon our contemporary's veracity or competence as a witness to the comparative accuracy of consumers' electricity and gas meters. A charge of this kind is only to be ignored at the price of a very obvious conclusion.

Comment is superfluous.

The Royal Society.—Among the Papers down for reading yesterday was "The Circulation of the Surface Waters of the North Atlantic Ocean," by H. N. Dickson.

Telegraphists in the Army.—It has been decided to enlist 60 more Post Office telegraphists for the Royal Engineers, the services of more operators being urgently needed in the field.

Personal.—The King of the Belgians has conferred the decoration of Knight Commander of the Order of Leopold upon Mr. Windsor Richards, past president of the Institution of Mechanical Engineers and of the Iron and Steel Institute.

The 1,000 Miles Motor Car Ride.—The greater number of the motor cars which left London recently on a 1,000 miles tour arrived back in town on Saturday night. A correspondent asks if this may be called a *tour de force*. The cars are now on exhibition at the Crystal Palace.

Nominations for F.R.S.—Among the candidates for the Fellowship of the Royal Society, announced at the meeting of the Society on Thursday last, are the following:—G. J. Burch, J. G. MacGregor, D.Sc., T. Muir, W. J. Sell, James Walker, D.Sc., and C. T. R. Wilson, M.A.

Wireless Telegraphy in the Russian Navy.—The St. Petersburg correspondent of the *Daily Mail* states that, in consequence of the success attending the experiments with M. Popoff's system of wireless telegraphy, the Russian Naval Minister has decided to introduce it into the navy. The whole of the Black Sea fleet will, our contemporary says, be fitted with the necessary apparatus this summer.

"Electrical Measurements."—A special course of 10 lectures, with laboratory work, on "Electrical Measurements for Electrical Engineers and Electricians" will be given at the Borough Polytechnic Institute, Borough-road, London, S.E., by Mr. John Henderson, D.Sc. (assisted by Mr. H. S. Saunders), on Monday evenings, from 8 to 10 p.m., commencing May 21. The course is intended only for students having some elementary knowledge of electricity. The syllabus is set out in an advertisement on another page, which also contains some further particulars.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Latakia—Cyprus	June 21, 1899 ...	—
Cayenne—Pinhieros	Oct. 11, 1899 ...	—
Tangier—Tarifa	Jan. 3, 1900 ...	—
Paramaribo—Cayenne	Feb. 16, 1900 ...	—
Ceara—Maranham	Feb. 20, 1900 ...	—
Pará—Maranham	Mar. 2, 1900 ...	—
Môle-St. Nicolas—Cap Haitien	Mar. 7, 1900 ...	—
Manila—Iloilo	April 9, 1900 ...	—
St. Dominguez—Curaçao	May 6, 1900 ...	May 13, 1900

A Double Tariff Aron Meter.—A modification of Dr. Aron's meter, converting it into a double tariff meter, is described in the *Electrotechnische Rundschau* of May 15. The principal parts of the meter itself are precisely those of Dr. Aron's latest pattern of ordinary meter, but there are two sets of dials instead of one, and next to each is a clock-face with a pointer similar to that of an alarm clock, which is set to the time at which that set of dials is to come into action. By a simple addition to the clockwork gear of the meter, one or other of counting trains is geared to the driving wheels of the meter according to the time.

A Large Double-Current Generator.—There will be shortly installed in one of the stations of the Chicago Edison Co., says the *Electrical World* of New York, a new generating unit,

Digitized by Google

possessing many interesting features in point of size. It is stated to be the largest double-current generator yet constructed. It has a rated capacity of 2,500 kw., and will supply from the same winding continuous current at 240 volts or three-phase currents for transformation to 4,500 volts. The machine will have 40 poles, and will run at 75 revs. per min., and will be worked in parallel on the alternating as well as on the continuous-current circuit. It is expected that this machine will admit of being safely worked with a 40 per cent. overload for one hour.

Obituary.—The death is announced of Mr. Edward Pritchard, which took place suddenly at his residence in Birmingham on the 7th inst. Mr. Pritchard was well known as a mining, waterworks and tramway engineer. In the last capacity he was responsible, among other schemes, for the cable tramways installed in Birmingham, and was the original adviser to the Birmingham Tramways Co. for the change-over on one section of their lines to the accumulator system of electric traction. He was also consulting engineer for the Carlisle tramways, now in course of construction. But a few days ago, he gave evidence before the House of Commons Committee in support of the bills of the London United Tramways Co., and of the South Lancashire Tramways Co. He was in his 63rd year at the time of his death.

A Russian Water-Power Scheme.—According to the *Engineer* an important water-power scheme in connection with the Dnieper is reported to have been formulated by an English company. At the point where the Dnieper takes a south-westerly direction in order to discharge itself into the Black Sea, near Kherson, it passes a succession of rapids. The company proposes to render the waterway navigable by constructing locks. The necessary capital, amounting to $4\frac{3}{4}$ millions, will be found by the company, while the Government is to guarantee 3 per cent. interest on this sum. The company seeks permission to utilise the power of the rapids for the generation of electricity over a period of 80 years; the Government, however, is to have the option of purchasing the undertaking at the end of 80 years.

Machinery for Canada.—The editor of the *British Columbia Review*, writing to the *Engineer*, points out that the Canadian Government has increased the preferential rebate from 25 per cent. to $33\frac{1}{3}$ per cent. in favour of British manufacturers, thus offering unique opportunities to British machinery of all kinds. This $33\frac{1}{3}$ per cent. rebate, it is claimed, is sufficient to enable the British manufacturer to compete successfully with the Americans. The demand for boilers of all kinds, mining machinery and accessories, dynamos, hoisting engines, turbines, &c., extends throughout Canada. In conclusion, it is suggested that so important is the $33\frac{1}{3}$ per cent. rebate, in view of the immense mining and industrial developments of Canada, that those who enter the field now will have an immeasurable advantage over those who follow later.

Fire at the Paris Exhibition.—The fates appear to be against the completion of the Paris Exhibition, and more particularly of the electrical section. On Tuesday morning a fire occurred in the cellars of the Château d'Eau, which contains the electrical machinery, not only for illuminating the waterfall and fountain, but also, it appears, for lighting the Palais de l'Electricité. Like other parts of the Exhibition, this installation was behindhand, and it appears that just previously to the outbreak the workmen were completing the connections to the switchboards in the cellars beneath the basins of the fountains. While the men were away at lunch a strong smell of burning was noticed, and it was discovered that some of the woodwork in the cellar was in flames. The fire was extinguished within 10 minutes, but not before all the connections to the switchboards were destroyed.

The Blondlot Electricity Meter.—The following description of this meter is taken from an abstract in the *Journal* of the Institution of Civil Engineers. One bobbin oscillates below a second bobbin in such a manner that the quantity of electricity which passes in the circuit during one oscillation remains constant, irrespective of the intensity of the current. These oscillations are registered and counted, and their number indicates the total quantity of electricity which has passed through the meter, the actual amount being obtained by multiplying this number by a constant q, the value of which is known. The apparatus is very sensitive, is instantly started, and conforms to the most abrupt variations of current. The apparatus employing neither a magnet nor an iron core, can be used for alternating as well as continuous currents. A full description, with diagrams, of the meter is given in the *Mémoires de la Société des Ingénieurs Civils de France*, 1899.

International Association for the Advancement of Science, Art and Education.—A meeting of the above association was held on Friday afternoon last, in the hall of the Society of Arts, when Prof. Patrick Geddes delivered an address on the aims of the association and its forthcoming assembly at the Paris Exhibition. Prof. Geddes explained that the Association had its origin in the strong conviction felt that the time had arrived for the constitution of that international association which had often been discussed and had never quite taken form. In response to a circular inviting co-operation, upwards of 500 members of the British Association had expressed their heartiest approval of the scheme, and agreed to form part of the committee. The members of the French Association and of the Paris Exhibition and the Paris University had likewise welcomed the proposal. Lectures would be delivered and congresses would be held, and the chairman (Prof. Archibald Geikie) expressed the hope that the success of the Paris meeting would be such that they would be able to connect the various scientific organisations throughout the world in a far more friendly way than had ever before been possible.

Embarras de Richesse.—In Monday's *Glasgow Herald* two advertisements proffering telephone service to the citizens are published. The first of these, which is headed "Corporation Telephones," appears rather premature. It offers, however, an unlimited service at five guineas per annum, or a toll service at £3. 10s. per annum, plus 1d. per outward call, on one-year agreements. The second advertisement is by the National Telephone Co., and is headed "Some Reasons against Joining an Opposition Telephone Exchange in Glasgow." It points out that subscribers to "an opposition telephone exchange" would have no intercommunication with the 8,000 Glasgow subscribers of the National Telephone Co., and explains that the former would have to pay terminal fees to the National Co. with respect to conversations with subscribers outside the Glasgow telephone area. The National Co. offers an unlimited service at £10 per annum for the first instrument, and £8. 10s. for the second, or a toll service at £3. 10s., and 1d., the latter being the same rate as the Corporation offer. The advertisement continues: "These rates . . . . . are infinitely cheaper than the £5 or £6 proposed to be charged for talking to the comparatively small number who can be connected to any merely local opposition system." It is added that the National Telephone Co. are re-arranging their Glasgow system, and that in a few months all their Glasgow subscribers will have a double-wire service.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

(To-day) FRIDAY, May 18th.

INSTITUTION OF JUNIOR ENGINEERS.

8 p.m. Ordinary Meeting at the Westminster Palace Hotel, Victoria-street, S.W. Paper to be read: "A Short Review of the Motor-Car Industry," by B. H. Joy and C. H. Rush.

ROYAL INSTITUTION.

9 p.m. Evening Discourse on "The Structure of Metals," by Prof. J. A. Ewing, F.R.S.

THURSDAY, May 24th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Annual General Meeting at the Society of Arts, John-street, Adelphi, for Members, Associate Members and Associates only, to receive the Annual Report of the Council, and Statement of Accounts and Balance-Sheet for the year ended December 31, 1899.

FRIDAY, May 25th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Agenda: (1) Experiments illustrating the Aberration called Coma," by Prof. S. P. Thompson, F.R.S.; (2) "Notes on the Measurement of some Standard Resistances," by R. T. Glazebrook, F.R.S.; (3) "On the Strength of Ductile Materials under Combined Stresses," by J. J. Guest.

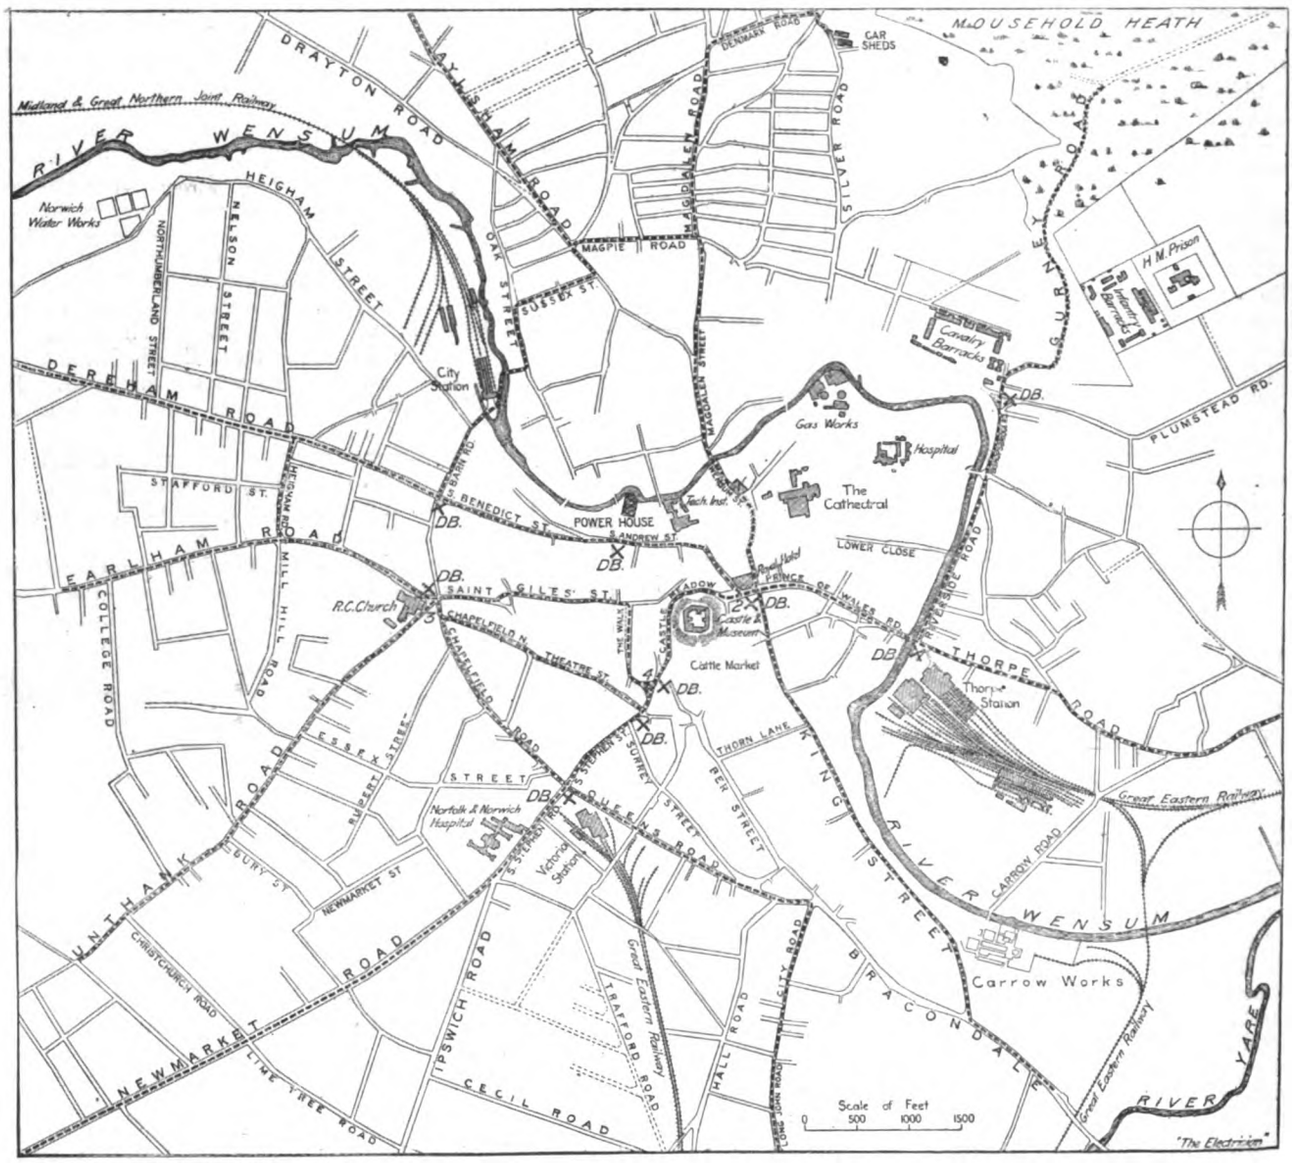
NORWICH ELECTRIC TRAMWAYS.

Up to the present time the ancient city of Norwich has not possessed a tramway of any description. The impending opening there of some 20 miles of electrically equipped tramways, therefore, marks an important event in the history of the city. The event is also of no small importance in the history of electric traction in this country, for it has hitherto been the custom in British cities to commence the experiment of electric traction with but a few miles of trolley line. At Norwich, however, no less than 20 miles of track have been equipped for this, the first stage of the tramway system, the present tramways being so laid out as to form a substantial backbone for further extensions over the municipal area.



——— Tramway Routes. X *DB*—Distributing

MAP OF NORWICH ELECTRIC TRAMWAYS.

Before describing this new tramway system we may state briefly the history of its development. In January, 1897, the Borough Council had under consideration two opposing schemes for the construction of tramways and light railways, one by the New General Traction Co., and the other by the British Electric Traction Co. In April of that year a committee of the Council recommended the adoption of the first named scheme, and this recommendation was approved by the Council in the beginning of May. A bill was promoted by the New General Traction Co. for the incorporation of the Norwich Electric Tramways Co., with a capital of £240,000 in shares and borrowing powers up to £80,000. The bill provided for the construction of 5 miles 24 chains of double track and 11 miles 17 chains of single track. It came before a House of Commons Committee on May 31, 1897, and was not oppose

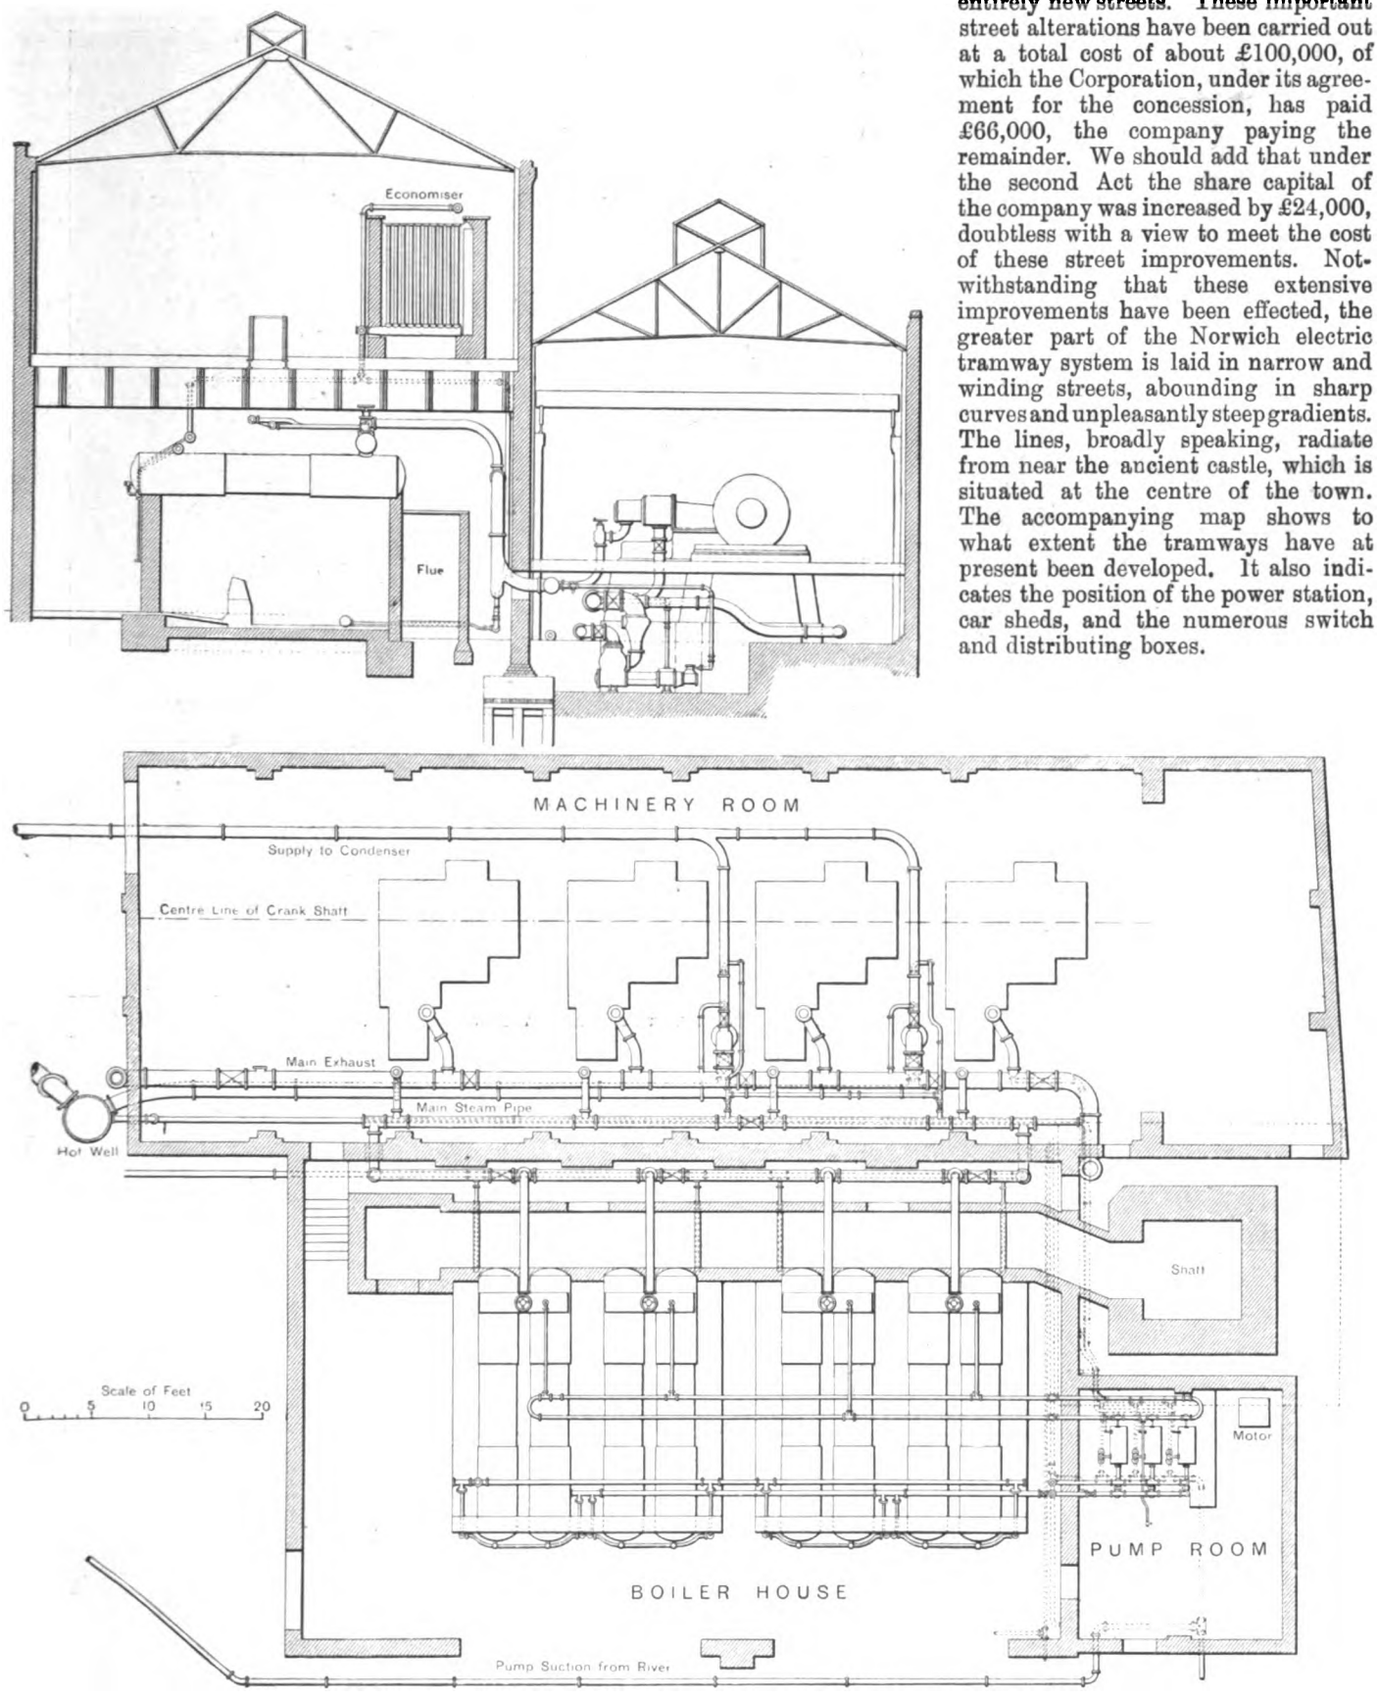
GROUND PLAN OF POWER STATION.

The "compulsory purchase" clause provided for a period of 50 years before the clause could be enforced by the municipality. The work of constructing these tramways was commenced at

Digitized by Google

the end of 1897, the contract for the entire equipment being let to Messrs. Pauling and Co. (Ltd.), of Westminster. It was found, however, that this Act did not make sufficient provision for the development of a suitable tramway system, chiefly owing to the narrow and winding character of the streets of the ancient city. A new bill was therefore brought before Parliament in 1898, for powers to construct additional tramways having a length of 14 chains of double track and 68 chains of single track, and to make extensive street alterations, including the widening of seven and the construction of two entirely new streets. These important street alterations have been carried out at a total cost of about £100,000, of which the Corporation, under its agreement for the concession, has paid £66,000, the company paying the remainder. We should add that under the second Act the share capital of the company was increased by £24,000, doubtless with a view to meet the cost of these street improvements. Notwithstanding that these extensive improvements have been effected, the greater part of the Norwich electric tramway system is laid in narrow and winding streets, abounding in sharp curves and unpleasantly steep gradients. The lines, broadly speaking, radiate from near the ancient castle, which is situated at the centre of the town. The accompanying map shows to what extent the tramways have at present been developed. It also indicates the position of the power station, car sheds, and the numerous switch and distributing boxes.

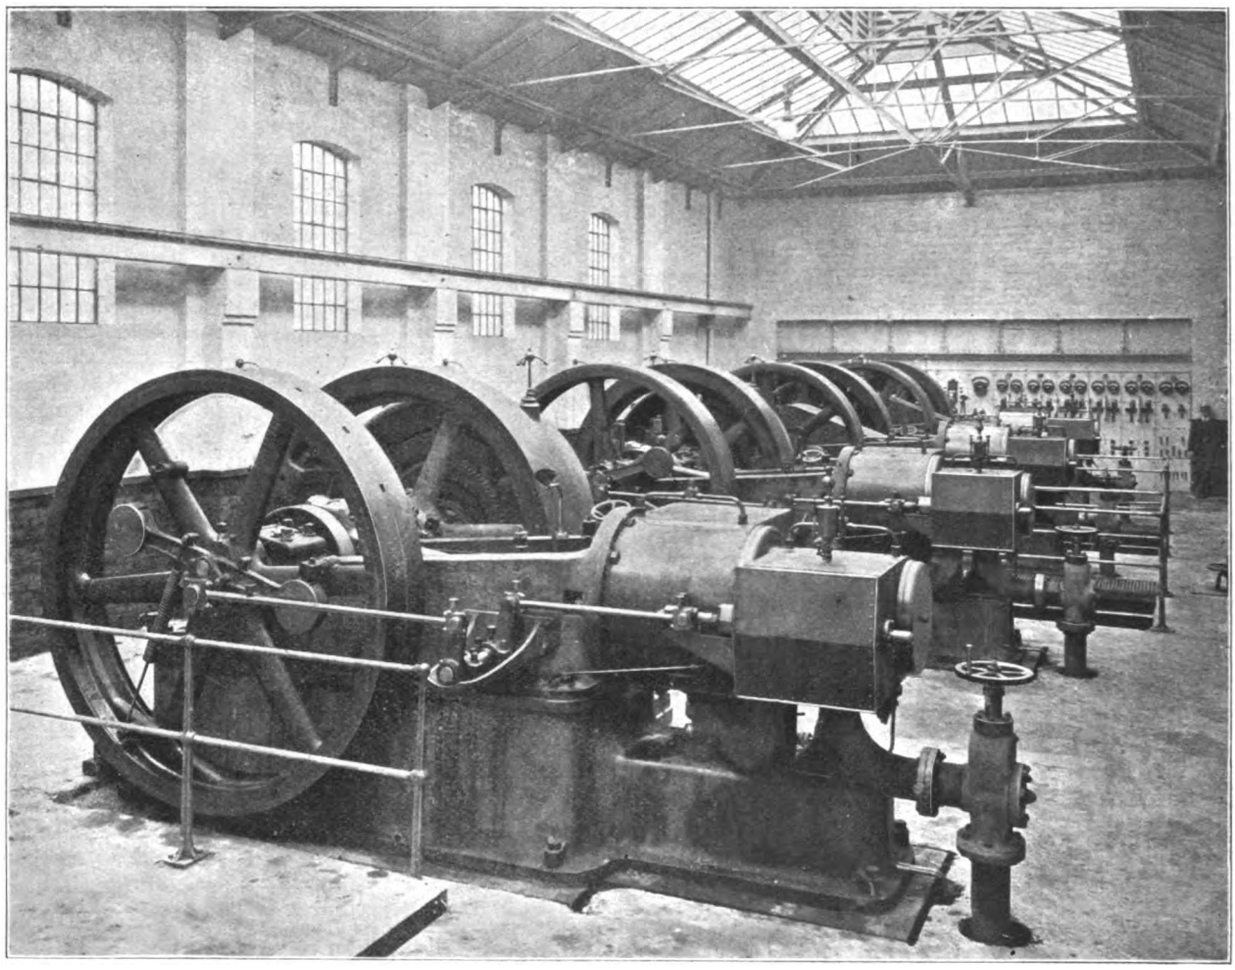


NORWICH ELECTRIC TRAMWAYS: PLAN AND ELEVATION OF MACHINERY AND BOILER ROOMS AT POWER STATION.

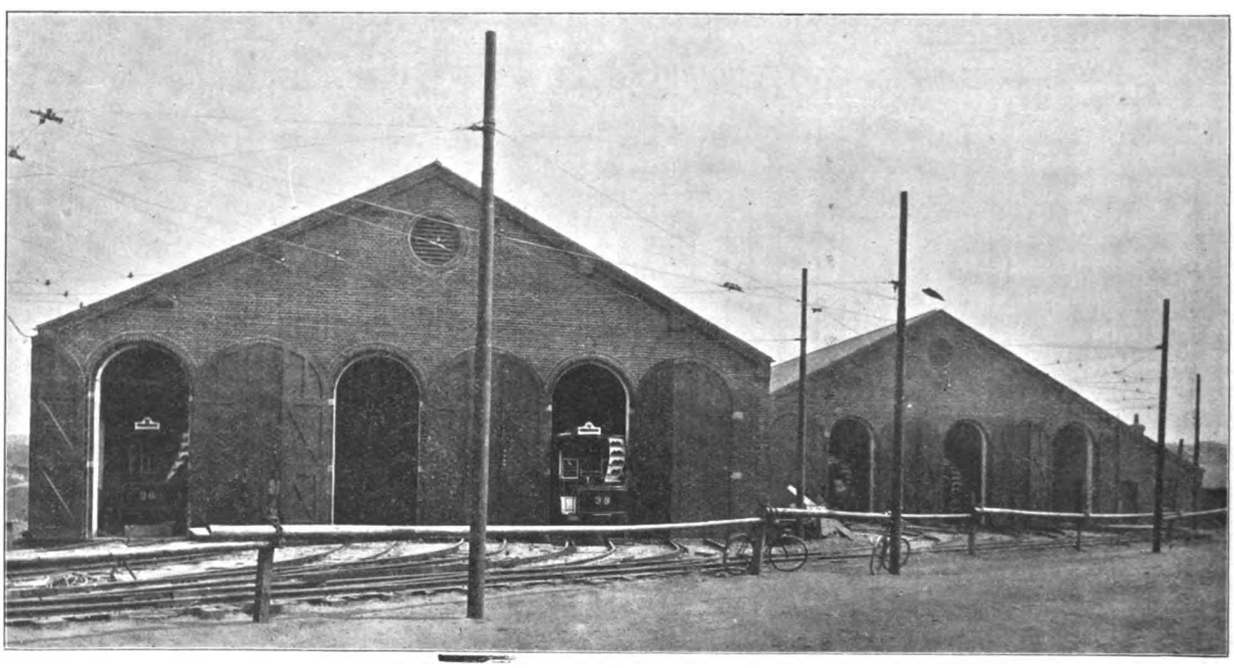
Some idea of the difficult nature of the ground over which these tramways have been laid will be gathered from the following particulars. The minimum radius is situated at the junction of Red Lion-street and Rampant Horse-street, and is

Digitized by Google

35ft. in length. The sharpest gradient curve is situated at the turning of Queen's-road into St. Stephens-street, and takes place on a gradient of 1 in 18. It is composed of curves of 70ft., 42ft. and 50ft. radius. The sharpest gradient is at the Whitehall Hill, and is 1 in 12. Numerous curves and gradients nearly as difficult as these examples abound, and in several places the roads have had to be terraced owing to the depression which would otherwise have occurred on the outer side of the curve.



Machinery Room at Norwich Electric Tramway Power Station.



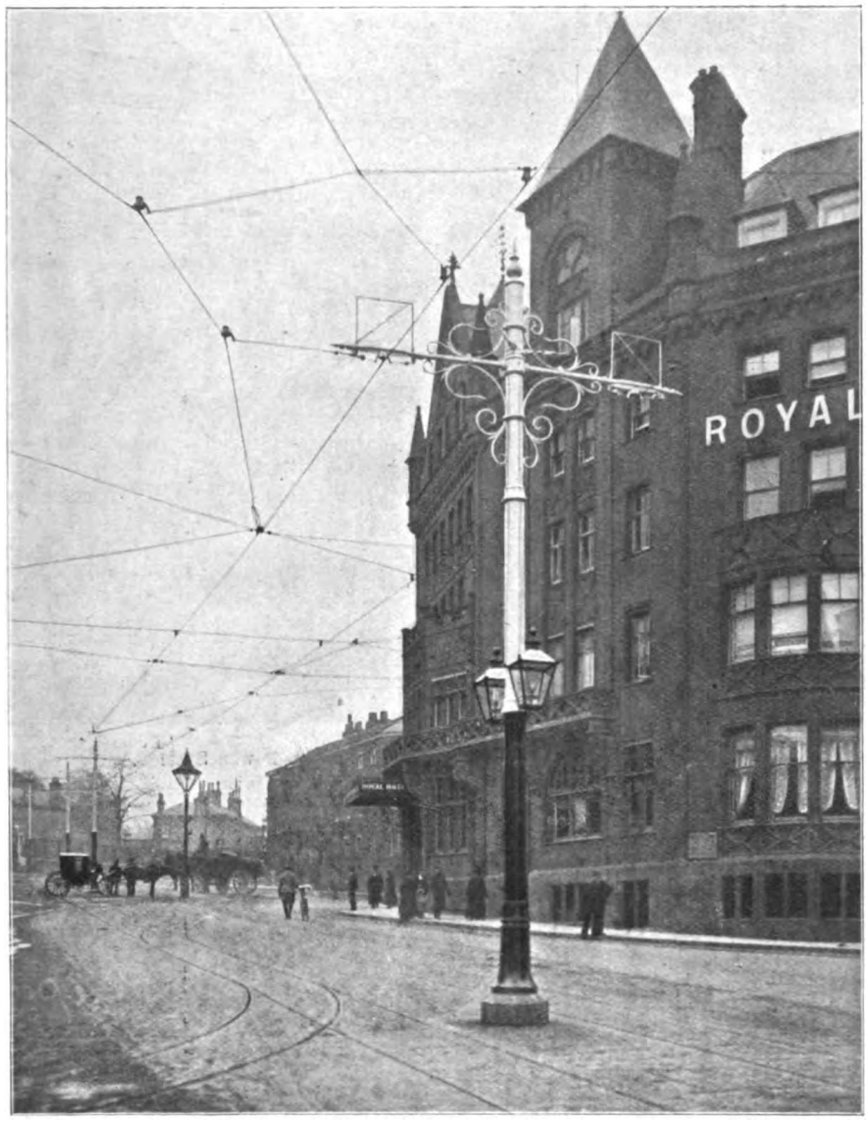
Norwich Electric Tramway Car Sheds.

The general character of the construction work and electrical equipment carried out in connection with these tramways is indicated in the accompanying set of illustrations from

Digitized by Google

recently-taken photographs. These show the interior of the spacious machinery room at the power station, which is very suitably located near the centre of the tramway system, and on a site adjoining the River Wensum, by which coal and condensing water are readily obtained. This station is of 1,280 H.P. capacity, and is equipped with Browett - Lindley engines direct coupled to Westinghouse generators, steam being supplied from Babcock-Wilcox boilers. Views are also shown of the front and back of the switchboard, and of a typical portion of the track work and overhead equipment; also of the car sheds and workshops and of the type of motor car adopted.

These tramways are constructed on a 3ft. 6in. gauge, of cast welded 45ft. steel rails, weighing 65½lb. per yard on the straight, and up to 90lb. for guard rails on the sharp curves. The numerous and often difficult points, &c., have been successfully carried out by means of Messrs. Askham Bros. and Wilson's patent automatic fixed points, which have been extensively used on the tramways of this country and abroad. For some parts of the Norwich track the same manufacturers have supplied their movable and open points of crucible cast steel. We shall describe this "special work" later in the article. The equipment includes 40 motor cars and 10 trailers, it being intended to run 36 motor cars, with a varying number of trailers according to requirements. There will be a 10-minutes service of cars on all routes between 6 a.m. and 11.15 p.m. The cars are double decked, and each has a capacity of 52 passengers, 26 outside and the same number inside.



NORWICH TRAMWAYS: VIEW SHOWING CENTRE POLE AND OVERHEAD EQUIPMENT OF SPECIAL WORK SHOWN AT "2" ON THE MAP.

The electrical equipment of the track of these tramways has been carried out on the overhead trolley system. The details of its construction, however, are remarkably varied owing to the peculiar nature of the route. A separate forward and return trolley wire has, of course, been employed throughout the system, even on those portions of it which are of single track. Over some parts of the route these are carried on ornamental centre poles with double brackets, as shown in one of our illustrations. In other places side poles with single brackets of varying length are employed. Again, in other places side poles on both sides of the streets with span wires are used; while in very narrow streets span wires with wall rosettes have been erected. In one or two places where rosettes were

NORWICH TRAMWAYS: BACK OF SWITCHBOARD AT POWER STATION.

Digitized by Google

originally used it was found that the ancient builders of the houses had not used material sufficiently strong to withstand this unexpected strain; the rosettes came out and side poles had to be erected instead.

Most of the construction work has been carried out under sub-contracts, of which the various engineering firms concerned are as follows:—

Track, points, crossings, &c.	Askham Bros. & Wilson.
Track rails	Alex. Penney & Co.
Electrical equipment of track	R. W. Blackwell & Co.
Cast-weld joints of track	Do.
Peckham trucks	Do.
Cars	Brush Electrical Engineering Co.
Car Equipment, including motors, controllers, &c.	Westinghouse Electric Co.
Feeders	British Insulated Wire Co.
Section and distribution switches	Westinghouse Electric Co.
Switchboard	Do.
Generators at power station	Do.
Steam engines	Browett, Lindley & Co.
Boilers	Babcock & Wilcox.
Stoker and conveyor	E. Bennis & Co.
Economiser	E. Green & Son.
Pumps and condensers	Worthington Pumping Engine Co.
Steam feed exhaust piping, &c.	Babcock & Wilcox.

In the remaining portion of this article which, owing to pressure on our space, we are obliged to hold over until a future issue, we shall give to our readers a technical description of the various departments of the tramway system, together with additional scale drawings and plans of important parts of the work.

(*To be concluded.*)

THE ELECTRICAL EQUIPMENT OF SHIPS OF WAR.*

BY C. E. GROVE.

(*Continued from page 49*).

Efficiency.—The mechanical efficiency of an electric motor is as a rule a few per cent. higher than that of a steam engine of corresponding power. The efficiency of the system as a whole involves the consideration of the generating and distributing arrangements, and here electricity has a marked advantage over either steam, compressed air, or hydraulics, the power taken being strictly proportional to load and the overhead efficiency from indicated horse-power of generators to brake horse-power on motor shafts averaging about 65 per cent. at full load. Efficiency, however, cannot be considered alone. The naval architect wants the relative advantages of competing systems expressed in terms of weight and space. In a given ship of war, the correct adjustment of weights and dimensions is correlated with the maximum offensive and defensive qualities involved in armour and armament, speed, and coal endurance. Hence, unscientific as it may appear in itself, an electric power distribution system of high mechanical efficiency may be a positive disadvantage to a warship if the weights involved conduce to an unfavourable design in the offensive and defensive qualities of the ship. Whether the change from steam to electric driving of auxiliaries involves the sacrifice of greater weight than is compensated for by the advantages gained is precisely the question on which authorities differ—the differences being chiefly due to the use of general terms for the sake of the argument instead of precise calculation. The main sources of loss in operating steam-driven auxiliaries are three: (*a*) The use of too great a range of temperature and pressure in the cylinders; (*b*) Leakages past pistons and valves due to wear; (*c*) Steam pipe condensation.

(*a*) As illustrating the uneconomical use of steam under the first condition, consider the case of winches and capstans. These must exert a powerful effort in starting, and hence must have very little lead and lap to their valves. If therefore steam at or near boiler pressure, say 250lb, be taken with cut-off at, say three-quarter stroke, and discharged into the condenser at the end of the stroke, it is obvious that the steam consumption per indicated horse-power must be very high. Steam engineers are well aware of this, and the increase in boiler pressures of the last few years has led to the introduction of several methods of utilising steam in auxiliary machinery to better advantage. One obvious but not-too-commonly-employed method is the use of reducing valves in the steam supply pipes of auxiliary engines. The favourite practice at present in the American Navy is to turn the exhaust from the auxiliaries into a feed-water heater, in which the latent heat is abstracted and the feed raised from about 80°F. or 85°F. to approximately boiling point; and when the power being developed in the main engines is too low for the feed to condense all the auxiliary exhaust steam, the surplus has been turned into a low-pressure evaporator. Notwithstanding the increase of back pressure on the auxiliaries by this arrangement, a saving of about 9 per cent, of coal used for auxiliaries is said to have resulted. In our navy, auxiliary feed heaters are being introduced for the same purpose. Other devices for economising steam are: the employment of compounding devices for using the steam in stages, as, for example, operating some auxiliaries by the exhaust from others, supplying auxiliaries at full pressure and exhausting into the intermediate receiver of the main engines, or drawing supply for the auxiliaries from the intermediate or low-pressure receiver and exhausting into condenser. All these systems have serious attendant disadvantages. Finally, some pressure is being put upon manufacturers of steam plant to improve the performance of the smaller engines by compounding, improving cylinder ratios, and so on.

(*b*) The losses that may occur in steam engines due to the effects of wear are most strikingly brought out by Mr. W. W. White, in his well-known Paper on the "Steam Consumption of the Main and Auxiliary Machinery of the U.S.S. 'Minneapolis.'"* These tests, which ultimately embraced all the machinery, were instituted in the first place to measure the steam consumption of the dynamo engines, which was known to be abnormally large, due to leakage past the pistons from the effects of wear. The pistons were originally grooved for water packing, and were without packing rings; new cast-iron pistons with snap rings were designed and fitted to one of the three dynamo engines, and tests made to ascertain whether the saving was sufficient to warrant the change in the remaining two. The engines were two-cylinder simple vertical inverted engines driving dynamos of 300 amperes capacity at 80 volts at 400 revs. per min. The engine cylinders were each 10½in. diameter by 5in. stroke, and were large for their work. Steam was supplied at 142lb. boiler pressure, and the exhaust condensed and weighed. The following results were noted:—

Set.	Load I.H.P.	Steam lbs. per I.H.P. per hour.	Remarks.
No. 1	21·873	123·27	Pistons water-packed and bad fit to cylinders cylinder bores rough and pitted.
do.	19·598	88·64	New pistons with 2 cubic in. packing rings
	33·601	68·25	in each, in use about ten days.
do.	29·184	69·33	New piston with packing rings in cylinders.
No. 2	19·012	108·71	Water-packed pistons, cylinder bores
	30·354	84·03	rough.
do.	16·791	102·73	Ditto ditto
	26·553	84·74	
do.	22·923	65·12	New pistons with packing rings, in use about
	35·237	56·45	nine days.
No. 3	17·324	97·75	Water-packed pistons; fit cylinders closely.
	26·234	79·48	Cylinders in good condition.
do.	18·241	81·62	New pistons with packing rings, in use about
	27·815	72·14	four days.
do.	20·40	97·92	Water-packed pistons.

The chief source of loss is evident enough here, but even the improved results leave much to be desired. How much loss was attributable to similar causes in the case of the other auxiliaries was not investigated, but the results were in all cases extremely bad. There is no corresponding loss due to the effects of wear in the case of electro-motors.

(*c*) Condensation in the steam pipes is probably the most serious of all the sources of loss. If we allowed that in the progress of design the average steam consumption in pounds of *dry* steam per indicated horse power of all the auxiliaries were brought down to the level of that of the dynamo engine—the most efficient auxiliary in the ship—the margin of loss from condensation to be got rid of by the extended use of electro-motors would go a long way to furnish the required set-off in coal saving to balance the necessary increase in weight of the electric system. For it is to be remembered that this loss occurs not merely when the auxiliaries are exerting power, but goes on the whole time the ship carries steam, whether the engines are working or not. To illustrate this point, an instance may be mentioned that has recently come under the author's observation. The new first-class battleship "Shikishima" carries 25 Belleville boilers, capable under full steam of developing over 15,000 I.H.P. in the main engines, besides working the auxiliaries necessary for steaming at full power, driving dynamos, &c. Thus each boiler at full power is equal to the supply of steam for over 600 I.H.P. When at anchor, one boiler under easy steam—*i.e.*, evaporating from 9lb. to 10lb. of water from and at 212°F. per pound of coal—was just able to work one 48 kw. steam dynamo at about half power, together with one feed-pump and the air and circulating pumps connected with the auxiliary condenser into which the dynamo engine exhausted, besides working a fire- and bilge-pump occasionally. If a capstan engine or boat hoist had to be worked in addition, a second boiler was necessary. The dynamo was about 160ft. of pipe length away from the boiler,

* Paper read before the Institution of Electrical Engineers, April 26th.

* *Journal* Amer. Soc. Nav. Engineers, February, 1898.

Digitized by Google

the total range of steam pipe connected being 500ft. to 600ft. Performing the first-mentioned service with only one boiler alight, the coal burnt varied from 3½ tons to 5 tons per day of 18 hours for about 65 I.H.P., or about 7lbs. per I.H.P. hour at the best to 10lb. at the worst, the average being over 8lb.; which shows that more than half the fuel must have been expended in keeping the pipes warm. All pipes were well covered and below decks, and all machinery new and in first-class condition. Sir John Durston has published particulars of the coal consumption of certain auxiliaries of H.M.S. "Diadem," obtained when the ship was at rest in the basin, which bear on the same point.* He discovered that to run one main feed pump, one blowing engine, one auxiliary circulator, one electric light engine, and two distiller pumps consumed coal at the rate of 6·1 tons per day when two extreme forward boilers were employed, or 3·88 tons when two extreme after boilers were employed; the same machines with the addition of two evaporators, working compound, consumed 8 8 tons per day when supplied from the forward boilers, and 7 09 tons when supplied from the after boilers—*i.e.*, the elimination of the lengths of steam piping between the forward and after boilers alone resulted in a saving of from 20 to 30 per cent. of the total coal used for the machines in question. The same proportion of waste may be concluded to exist under sea-going conditions; for although more machinery would be at work, and therefore the steam would in some measure be used to better advantage, yet, on the other hand, the long lengths of pipes fore and aft of the ship would be connected to the steam mains, as well as branches going into colder regions above the protective deck. Hence it is clear that with short, direct connections to steam dynamos, and electric distribution to all the other auxiliaries for which electric driving is suitable, a considerable saving of coal—probably at least five tons per day—would be effected under this head. The total coal consumption for auxiliary purposes may be thus computed: Steaming at "economical" speed—about 12 knots—involving, say, one-fifth power, it is known that the coal consumption of a good modern first-class battleship or cruiser with Belleville boilers fitted with economisers is about 2lb. of coal per indicated horse-power-hour, which for 3,000 H.P. represents about 65 tons per day of twenty-four hours, of which the minimum number of auxiliaries employed under these conditions (*i.e.*, steering, engine pump, distiller, and one dynamo) consume on an average about 25 per cent. =16 tons. Supposing the engine-room pump continue to be steam driven, the principal auxiliaries used when the ship is cruising under ordinary sea-going conditions will be, besides those mentioned, ventilation fans, ash-hoist engines, and refrigerating machinery, together with air compressors and turret machinery for drill purposes. These machines work intermittently, and hence average coal consumptions are to some extent a matter of speculation; but it will probably be below the actual consumption of many ships to take the average total coal consumption of all the auxiliaries employed in an ordinary commission at 20 tons a day,† or, neglecting the dynamo, 15 tons.

Turning to the broad question of the mechanical efficiency of electrically-driven auxiliaries, notice must be taken of a couple of recent Papers by Lieut. Robinson, U.S.N.‡ For purposes of comparison Lieut. Robinson takes the average steam consumption of the best steam auxiliaries now produced at just below 70lb. per indicated horse-power-hour. He puts the best steam consumption of an electrical generator at 26lb. per indicated horse-power-hour, the exhaust being taken into a feed heater. He takes the efficiency of the engine at 93 per cent.; dynamo, 86 per cent.; line, 95 per cent.; and motor, 78 per cent. = overall efficiency, 59 per cent.; and on this basis shows that the steam consumption per brake horse-power on the motor shaft is 44lb. per hour, representing a reduction of 35 per cent. of the steam used by the best steam-driven auxiliaries. He then goes on to argue that if electric motors are used to drive the auxiliaries it will be necessary, in order to get the requisite torque at the highest speeds, to instal motors of 1·5 times the rated horse-power that would be required if steam auxiliaries were used; and hence, that as against a total of 1,500 I.H.P. of steam auxiliaries weighing (at 100lb. to the I.H.P.) 70 tons, a total motor capacity, is required of 2,250 H.P., weighing on the same basis 105 tons. The author ventures to join issues with this conclusion, which appears to be incorrect in several particulars:—

(i.) The I.H.P. of steam-driven auxiliaries is compared with the B.H.P. of motor driven auxiliaries, which is unfair. It would probably be liberal to allow an average mechanical efficiency for steam engines of the class used for auxiliary machinery of 70 per cent., so that if they consume 70lb. steam per I.H.P. this represents 100lb. per B.H.P. Hence the saving of coal due to electric driving is 56 per cent. instead of 35 per cent. (ii.) The only auxiliaries requiring maximum torque at highest speeds are pumps and fans, and it does not at all matter whether the torque exerted by motors on such machinery is equal to that exerted by steam engines, or not, provided the useful work done per minute is the same; on the contrary, services of this kind are excellently adapted to the capabilities of motors of comparatively small torque but high speed, the high speed allowing of a smaller and more compact machine than the slower running engine. (iii.) Winches, capstans, turret and steering engines, and, in fact, all in which inertia effects come in, require maximum torque *at starting*. Here the electric motor is distinctly on its own ground, for it is quite easy to build and control motors in such a way as to obtain from them a starting torque equal to two or three times that corresponding to their rated full power, which is not the case with steam engines; besides which the motor has the further advantage of exerting a continuous rotary effort in lieu of the fluctuating turning moment of the reciprating engine. (iv.) The argument as to the higher power rating of the motor drive appears to be drawn from the analogy of electrically-driven as compared with steam-driven machine shops, which is inapplicable to the case under discussion.

The conclusion appears to follow from the foregoing arguments that any appreciable increase in the horse-power rating of electric, as against steam-driven auxiliaries is unnecessary, and that if the whole of the auxiliaries of a 15,000 H.P. ship were electrically driven a saving of about five tons of coal used in generating the auxiliary steam would result from the suppression of pipe condensation, and (on the rather low basis of 59 per cent. overhead efficiency) a further saving of 56 per cent. of the balance of 10 tons = 5½ tons, due to superior mechanical efficiency—a total of 10½ out of the 20 tons of coal per day used by a good steam auxiliary equipment. The total bunker capacity of a ship of the power mentioned would be about 2,000 tons, representing the ability to keep the sea for about 25 days at economical speed. The saving in coal consumption in these 25 days represents 262 tons on the basis shown—an amount sufficient to more than counterbalance the necessary additional weight of generators and motors carried.

The questions next arising are: To what purposes is it practicable, having regard to all considerations, to adapt electric driving, what would be the changes in weight, space, &c., involved and what should be the arrangement of the installation for supplying the power? There is a broad difference at once to be recognised between machines directly co-operating with the main propelling machinery and those performing other duties. On the whole, present engineering opinion is, from considerations of reliability, decidedly in favour of continued steam driving for boiler-feed-pumps, circulating and hot-well pumps, fire and bilge and distiller pumps. It happens that these pumps are the worst steam-eaters in the ship; in the "Minneapolis," for example, the consumption ranged from 75·74lb. in a circulating pump doing 4·1 I.H.P., one cylinder alone taking steam, to 318·68lb. for a small pump developing 0·78 H.P., which was used for flushing purposes, the average for the 12 pump tests included in Mr. White's tables being 161·61lb. per indicated horse-power-hour. Experience with electric auxiliaries in other situations may eventually lead to the use of electricity for these services; but this contingency may be left out of account for the present. Starting and turning engines may be regarded as parts of the main engines themselves, and, of course, will be driven by the same power. The only auxiliary services within the engine and boiler rooms for which the use of electricity may be considered at present are ventilation and furnace blowing.

Fans for Engine and Boiler Room Ventilation.—In the "Canopus" class of battleships each engine-room is ventilated by a 7ft. 6in. fan driven by a direct-acting steam engine, while the boiler-rooms are supplied with air from four 8ft. fans at 240 revolutions, and two 6ft. fans at 320 revolutions per minute. These represent in the aggregate about 150 I.H.P., with a weight of between three and four tons. The "Duncans" will carry two engine-room fans, each 6ft. 6in. in diameter, with two 8ft. 3in. and eight 6ft. 6in. fans in boiler-rooms, the speed being about 300 revolutions. Fan driving, being a purely rotary movement, is a duty which electric motors have shown themselves excellently able to perform; they can run at at least twice the speed of reciprocating engines for the same power without noise or vibration, and can give the required deliveries with smaller fans, with higher efficiencies in both motors and fans, and therefore with less total power. It would probably be reasonable to take the total power of motors to perform the engine and boiler room ventilation of the most powerful ships at about 80 B.H.P. on the fan shaft, say, 100 E.H.P. input, which could be provided in enclosed type motors built for continuous work at 750 revs per min. for about three tons, or, allowing for the weight of the fans, an increase of not more than one ton on the above total weight.

Furnace Air-Blowing Engines.—These are high-pressure air-pumps adapted for delivering air at 15lb. to 30lb. pressure above the fires and into the combustion chambers of the boilers. A set of five such engines in the "Shikishima" weigh 5 tons 2 cwt., and develop an aggregate of 220 I.H.P. Pumping services of this kind are very efficiently performed electrically, but the substitution of geared motors for engines would result in this case in an increase of the total weight, probably to the extent of about three tons for 200 E.H.P.

* *Transactions* of the Institution of Naval Architects, 1889.

† The "Powerful" is said to have burnt on her voyage to China last year 40 tons a day for auxiliaries. The "Diadem" crusiers and the "Canopus" battleships are, however, much more economical.

Furnace air engines are generally placed in the boiler-rooms, but if electrical they could more conveniently be placed outside or above the boiler-rooms, air-pipes only being led into the firing compartments.

Considering next the auxiliary machinery outside the engine and boiler-rooms we find these include steering engines, capstan engines, boat, coal and ash hoists, ventilating fans, air compressors, refrigerators, workshop engine, turret-working machinery, and ammunition hoists.

Steering Engines.—It is convenient to consider these machines in this section, as they are usually placed in the after steerage flat adjacent to the tiller compartment. In some of the latest British ships they are placed in the engine-rooms and connected by long lines of shafting to the tiller mechanism. This arrangement saves carrying steam pipes aft, but seems to have nothing else to recommend it.

Next to the main engines these are the most important in the ship, and before every question of weight or efficiency the most reliable machine must be used here. Electric steering engines have, the author understands, been made, and there seems no reason, so far as the motors are concerned, why equally positive results should not be obtained with these and with steam engines. The controlling of their motion is the principal difficulty. The motors would be everlastingly starting, stopping, reversing, and altering speed; or, if the motors ran continuously, then such movements would be always being made by the gears and clutches. And whereas the steering engine is deep down in the ship, the control has to be operated from distant stations, of which there are usually five, inter-connected, the forward bridge and conning tower being the most important and the most generally used. Simple rheostatic control from a distance is not good enough; to secure the necessary sensitiveness, a large number of switch contacts and connections would be necessary; and an extensive system of cables, inter-connecting all the steering stations is inadmissible. A maker of steering engines once told the author he had invented an electric steering engine which he was sure met every requirement, but it required 79 wires! The reply was, of course, that 79 wires would kill any such project. Recourse must be had either to a pilot motor, worked by a small switch and two or three wires, operating in its turn the controller of the steering motor proper (indeed, it would probably be possible to employ the hydraulic telemotor, now so largely used, for working electric controlling switches alongside the steering motors, in similar fashion to that in which it reverses the valves of the steam steering engine), or to the interaction of two machines as in the Ward Leonard system of controlling turrets. If the difficulty of control be satisfactorily overcome, the gain in efficiency of electric steering mechanism ought to be very substantial, owing to its long periods of work. From its irregularity of working it is impossible to define the average H.P. of a steering engine. The motor to replace it must be a substantial affair, heavily geared, the torque required on the rudder-post of a big battleship being as much as 500 ton-feet. To move the rudder from hard-a-port to hard-a-starboard in 30sec., which is the usual requirement, a steering engine will make about 300 revs., and working at this maximum rate the I.H.P. will lie between 300 and 400, and the useful work done on the rudder-post will be at the rate of about 75 H.P. net, an overall efficiency of 20 to 25 per cent. Each steering engine with its gear weighs 5½ to 6 tons; two sets are carried. If each steering engine were replaced by one motor capable of exerting the same starting torque, the full load rating of each motor on continuous work might be taken at 150 H.P., though the starting current allowed would correspond to twice this power. With electric driving, an improvement in efficiency might be expected. The extra weight involved, using open-type machines, would be about two tons per set.

Capstans.—The principal capstan is, of course, the forward one, which has to operate the heaviest anchors. Besides other stipulations, its engines (usually duplex) are required by our Admiralty to lift a weight of 35 tons at the rate of 25ft. per minute = 60 actual horse power. The maximum indicated horse power may be taken at 200, and the weight of the complete capstan with engines and gears is about 47 tons. If electric motors were substituted for the steam engines with the same gears this weight would be increased by about two tons. But with better-designed worm gears the work could be done electrically on the same total weight. The after capstan performs similar but lighter work, lifting 15 tons at 25ft. per minute = 25 actual H.P., say 75 I.H.P. In our latest ships, while the forward capstan is still steam-operated, the after capstan is specified to be driven by two reversible watertight motors, performing the above specified work at speeds not exceeding 750 revs. per min., and so designed that the rise in temperature after one hour's run at full load does not exceed 80°F. This change involves an increase of total weight in capstan, motors, and gear of from one to two tons. In lieu of two motors, the Admiralty have accepted for the "Duncans" and other ships an electric capstan driven by one 50 H.P. motor at 350 revs. per min., the weight of the complete capstan, motor and gear being approximately the same as that of the steam after capstan of H.M.S. "Albion." Fig. 30 shows the general arrangement of the electric capstan of H.M.S. "Irresistible," by Messrs. Clarke, Chapman and Co.

It will require a somewhat protracted experience to determine whether, on the whole, the use of electric motors for capstans proves advantageous. To be quite safe, motors should be used with a large margin of power, notwithstanding the increase of weight involved, for the stresses involved in such work are apt to rise with great suddenness to many times their average value, and capstan chains have a habit of jamming in the stops. If steam driven, the engine will pull up, and is able to stand under the load; a motor cannot do this, yet it can neither be allowed to burn up nor to relinquish its work by cutting itself permanently out of circuit. Special devices are necessary to meet such a condition. Mr. Siemens dealt somewhat fully with this matter at Dover, so it is unnecessary to dwell further

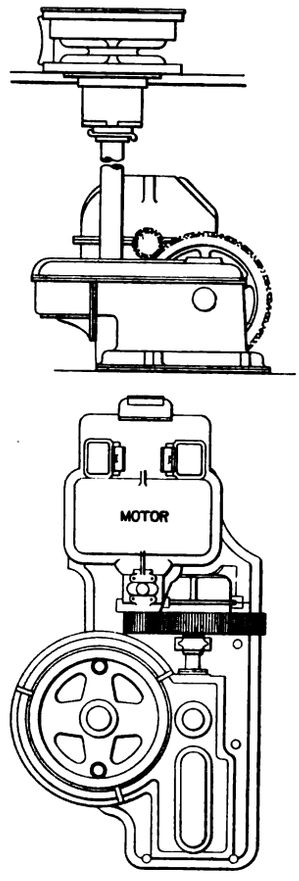

FIG. 30.—Electric Capstan, H.M.S. "Irresistible." (Clarke, Chapman & Co.)

upon it here. Neither in this case nor in that of the steering engines do there appear to be difficulties incapable of satisfactory solution electrically, and in these cases the longest steam-pipes in the ship are concerned.

(To be continued).

ON DISTANT ELECTRIC POWER TRANSMISSION.

The following is an abstract of the Discussion which took place at the Institution of Electrical Engineers on April 26th, in connection with Prof. George Forbes's Paper on the above subject:

The PRESIDENT (Dr. S. P. Thompson) said the Institution owed a great debt to Prof. Forbes for having read this remarkable Paper, which was the result of his own (Prof. Forbes') experience, and showed the reasons for his detachment from immediate connection with any one set of manufacturers or designers in whose favour he might otherwise have been biassed.

Prof. J. PERRY, who complained that he had not had time to study the Paper thoroughly, as it only reached him that same morning, asked for a little more information upon some of the practical points. For example, Prof. Forbes spoke of the use of synchronous motors for reducing the power factor. [Prof. Forbes: Increasing it.] One would like figures giving the actual size of the motor required. Again, there was very little information to be found anywhere about turbine details; lately, he (the speaker) had, only succeeded in getting civil engineering details about the position of turbines, and the dams for water, and so on. The old Paper written by Prof. Ayrton and himself about 20 years ago on the economy of conductors was very well worth study. There was another Paper published about the same time, which he believed had never been mentioned by anybody since it was published, and which referred not merely to the transmission of power to a distance, but to transmission of power by a conductor distributing power along the whole of its length, giving off equal amounts

Digitized by Google

of power per mile. He had had to take the matter up in connection with a telpher scheme, and had got some most interesting results, which were well worth studying at the present moment. He was not sure that he quite understood why it was that Prof. Forbes was trying to keep up the voltage in this transmission of power. Prof. Forbes spoke of the enormous dvantages in the transmission when there was a less efficiency than 50 per cent. It was proved to both Prof. Ayrton's and his own satisfaction—he did not know whether to anyone else's—that it was not possible to transmit with a less efficiency than 50 per cent., and he would like to know whether it was not likely that Prof. Forbes had neglected a rather important thing in this matter of boosters—viz., that the power developed in a booster costs money.

Mr. S. Z. DE FERRANTI, having congratulated Prof. Forbes on his Paper, said that, according to it, Prof. Forbes did not know that air-cooled transformers of 1,500 H.P. capacity were made in 1889, and set to work to the extent of some 7,000 H.P. on the London Electric circuits. Although they were placed on special troughs to receive the air blast, this was unnecessary, for they kept quite cool without it. The air circulation was very perfect, and the machines had this interesting feature: The insulation, which was ebonite, was supported in the centre of an air space between the primary and secondary, and therefore the heat from the conductors was not directly transmitted to the delicate insulating material—viz., the ebonite. These machines had stood remarkably well. Experiments were also made with air cooling on the three systems—viz., natural, forced, and the latter. These had all been patented, and would have been patented in the United States as well, only the patent was refused for the usual reason—viz., that in those days inventors in that country were allowed to "swear back," and whoever could "swear back" the hardest and give the earliest date got the patent. He noticed nowadays that there was a very distinct tendency to drop rotaries in favour of motor generators, and he himself was very positive about the advantages of the latter. His opinion was that a rotary was a very difficult and tricky thing, and more suited to water-power transmission with perfect driving than to the ordinary type of electric generation from steam engines. He had seen American built rotaries with the features described by Prof. Forbes (viz., a short-circuiting piece between the poles to receive the currents induced in them), hunt about as badly as they could, and it was a clever business to keep them in step. Where the whole of the installation was perfectly planned out, perhaps, it was not such a difficult matter. Motor generators were quite the things to have when dealing with power at the end of a long line, when continuous current was wanted. He was at a loss to understand why people should use induction motors. The latter had bad power factors, and a bad power factor was the most serious thing it was possible to have in alternate-current working. He was very glad that Prof. Forbes had shown the fallacy of the idea that the way to transmit power was three phase, and that three phase had the wonderful gift that nothing else had of transmitting power at the least possible cost. It was quite certain that, as Prof. Forbes had stated, the best system of transmission need not be the best system for dealing with the general distribution as well, and the question was complicated when they had to use a system for many purposes instead of for one simple purpose. He was now going to make a statement which most of them would probably think a very silly thing, but he would make it all the same, and ask them to remember it, and see what they thought of it a few years hence. He considered that a single-phase low periodicity alternating system was the best of all the systems. All the details were not yet commercially complete for using it to the fullest advantage, but of one thing he was quite satisfied. If they wanted to transmit power to a distance, and turn it into continuous current, the single-phase alternate-current system was the best, and especially if they did it on some of the lines shown in the top diagram of Fig. 4, and earth the centre of the alternator and earth the centre of their transformers at a distance, so as to maintain the pressure on each wire at a constant potential above the earth, instead of having the contents of one conductor going to earth, and then jumping up the pressure to double the amount on the other conductor. Single-phase alternate-current generators worked just about as perfectly, and were just as strongly held in as two phase, and the working of these was much more perfect than three phase. In fact, they formed the most perfect means of turning alternate current into continuous. The only thing they had not satisfactorily got was a single-phase alternate-current motor. This, however, was much more perfect than was generally known, and the last tests he had seen of a 50 ∿ alternate-current single-phase motor was in the case of a 6 H.P. machine, where the power factor was 81 per cent., and the efficiency 81 per cent. They would, therefore, see that it was not necessary to go a great deal further to make these motors most valuable, and bring them up to the level of multiphase motors. The reason that he spoke so strongly in favour of this matter was because of its great simplicity. The switch gear and all the rest of the apparatus in multiphase systems was becoming a matter of almost alarming complication. At any rate, it was very much more complicated than a simple single-phase system, and the same applied to the conductors. It was always cheaper to use big conductors, especially when they were insulated, and of course if they only had a single phase to transmit there were less conductors than in any other system. He admitted there were many cases where multiphase working was, for certain purposes, a necessity, but all the same he thought fashion entered into the matter as much as anything else, and once having got the idea they seemed to go ahead with it without waiting to study it. He thought he was justified in speaking of power transmission in this country: They all knew there were many people who were struggling and working and risking their money to get powers to transmit high-pressure current all over this country for the benefit of manufacturers, and to put us on an equality with other nations who had these advantages. They also knew the legal procedure. Take for instance, the case of a man convicted of murder. It was always possible to find an able lawyer who, however well convinced he might be that the man had committed the murder, was ready to do his utmost to get the man off, and what he wished to draw their attention to was that while there were the people who were promoting these power schemes in Parliament there were others who were in opposition. He was not taking one particular case. There ought to be sufficient patriotism, honour, and good feeling in this country among a great profession like theirs to fight for that profession and the advancement of science in this country; it was a great misfortune if anyone could be found to come forward to say anything which would enable Parliament, or people interested in Parliament, to stop any of these great enterprises from being continued and put into practice, and being used for the benefit of the country. We were in a backward enough position; we had had a hard enough fight of it and we still had to fight a large number of vested interests, but surely amongst their great profession there should be no professional man found who would put forward a single word to prevent any of these schemes being rapidly brought into practice.

Mr. G. L. ADDENBROOKE said that the Paper dealt chiefly with long transmissions, longer, probably, than we should deal with in this country—at any rate for some years to come. From what he had seen in the colonies there was a vast field for such transmission of power. One reason of our having nothing of the sort here was probably that manufacturers had nothing to guide them in the construction of plant, and they had not that incentive to go into the matter which arises from close contact. Most of these great undertakings arose not merely from the manufacturers or users, but from a combination of the two. He did not see how any successful manufacture of plant on a large scale for this purpose could be made in England for use in other parts of the world, unless there were opportunities of seeing such plant at work on installations in this country. Manufacturers in Germany and America had these benefits, but on the other hand, it was, as Mr. Ferranti had pointed out, a most deplorable fact that experiment in this country was absolutely prohibited. They could do nothing in this country without going to town councils, which meant obstruction. Supposing in the early days of railways the whole of the companies had been put under municipal control. Where would the magnificent railway system of this country be? The electrical part of such schemes as these was a secondary consideration; the thing could be done, and we did not want to quarrel whether it could be done better one way than another. We could do it, and it was for Parliament to give facilities for doing it, and unless we got some such opportunities we would never get the capital of this country into such schemes. He had frequently been asked during the last three or four years whether the Central London Railway would work and succeed, and he had always replied that if the City and South London Railway succeeded so would the Central London, which was exactly the same thing. About 18 months ago he was on the Continent studying polyphase working, and he would like to correct the very general impression that it was not possible to do respectable lighting off three phase. On some of the installations he had inspected, where power and lighting were both supplied three phase without the use of motor transformers, the lighting was very good indeed—good enough for all practical purposes. And there was also this important fact which was not probably altogether appreciated—viz., if they had a first-class engine driving an installation at constant periodicity, they might have, with a rotary transformer, very large variations of pressure on the line without effecting the continuous-current wire, because as long as the periodicity remained constant the rotary transformer tended to go round at the same rate and took more current.

Mr. W. B. ESSON asked if the booster system had been tested in actual working. With regard to the inefficiency of Kelvin's law, might he ask if Prof. Forbes had taken into account the cost of the generators, because it might so happen that, in a case where 6 H.P. were generated, to get one they would spend in generators, transformers, &c., far more than they saved in copper.

Prof. FORBES: Then don't use the system.

Mr. ESSON: But what I want to point out is that you must take into account the whole of the cost.

Prof. FORBES: Of course you must.

Mr. ESSON then referred to the matter of phase rectifiers, and suggested that the reason the Oerlikon Co. adopted phase rectifiers was not the reason given, but was because their generators had such a tremendous drop they had been obliged to use these rectifiers to get the pressure up, or else burn out their generators. He also asked if Prof. Forbes had any figures to show the difference obtained by stranding the copper wire instead of having it solid for the factor given in Table VII.

Mr. ROBERT HAMMOND said the Paper was read at a very important juncture, as next week five power system bills would come before a committee of the House of Commons, and the question as to whether England was to have long distance transmission or not had some chance of early settlement. In discussing the Paper, he emphasised Prof. Forbes' opinion on the very grave importance of a proper appreciation of Lord Kelvin's law. The mere mortgage value of interest upon the copper would not do. Prof. Forbes had suggested that it might be 15 per cent., but he did not think that the most sanguine of the promoters of the power bills were looking for as much as that, but a good solid round interest upon the copper such as would tempt Mr. Addenbrooke's friends in the City to put their money into the schemes. However, Kelvin's law was something which had better be talked about on another occasion. The real choice at the present time lay between two and three phase. On three phase Prof. Forbes had given his opinion, but Mr. Ferranti had given single phase as being the best in his opinion; but there was a popular idea that the power schemes would have to choose between two and three phase. He (the speaker) had spent a most interesting time during the past fortnight in investigating two and three-phase systems on the Continent. Of course the Continent might be—and often was—wrong, but at all events they plumped for three phase in new work. There were many cases where there were large single-phase works in existence, and where many

Digitized by Google

festly the network was very much more suitable for two phase split up into two single phases. At Vienna, where there were 19 plants all in a row, the works were being extended by two phase because this was more suitable for extensions to the present network, but in new places, where they had a clean sheet, such as at Mannheim, the system throughout was three phase. The author had mentioned that, in his opinion, a common return was an advantage in the cost of the cables, but he (the speaker) had made very careful inquiries among many engineers on the Continent, including Mr. Bláthy at Budapest, and there was a very strong objection to the use of a common return with two phase. This latter gentleman had also very strongly objected to two-phase work, and had gone so far as to say that if he had not got to transmit to a very long distance he would prefer to generate and distribute three-phase low-pressure current from a station in the centre of a town. When at Baden he was given particulars of what was to be done in the north of Italy. They were going to run a full-gauge railway, 100 miles in length, by three phase; generation was to be three phase, at 20,000 volts, with converter stations 10 miles apart to transform down to the lower pressure of 3,000 volts, and this 3,000 volts was to be introduced to the motors on the cars. His last point was to support Mr. Ferranti strongly in favour of motor generators rather than rotaries. He was in Frankfort on Saturday morning, where the whole of the tramways were being run by motor generators from a single-phase station. The single-phase current at 3,000 volts was brought to a central spot in Frankfort, and was there transformed by three 750 kw. motor generators distributing a continuous current of 550 volts to the tramways.

Mr. JAMES SWINBURNE said that when in 1881 Lord Kelvin's law was brought forward, people thought they had got hold of something new; but really the novelty consisted in its simplicity. Lord Kelvin happened to deal with a case where the laws were simple and they could get a simple mathematical expression which gave a good economy. But the general law—that the most economical arrangement was to invest capital in order to save revenue—had been known to every commercial man from the beginning of the world; the only difficulty was to calculate it. When they had something they could calculate definitely, then they had Kelvin's law, but as soon as they got into complicated departures from it they had not Kelvin's law. And a thing of that sort had happened that evening. Prof. Perry's illustration was purely a useless misapplication of arithmetic useful to professors, but of no earthly use to a practical man. There had been some little misapprehension about Prof. Forbes's remarks with regard to boosters. Suppose they were limited to use a maximum of, say, 10,000 volts. The booster enabled them to run that 10,000 volts all along the wire, and therefore they got the economy. They always used the highest volts they were allowed to instead of using the highest at one end and allowing it to drop at the other. He did not know whether any of the members ever beguiled away their leisure by tracing the origin of religious dogmas. It was a very interesting study, and he would like to deal a little in that direction with the rise of the three-phase motor. Some time ago, especially in Parliamentary inquiries, there was always the reproach against the alternate current that there was no alternate-current motor. The problem of the day was to solve alternate motors. Then came along Tesla and the people in Germany, and they professed to have solved the alternate motor problem. But they only introduced a new system of distribution which was capable of producing a motor which was not an alternating-current motor; it was another thing parading under the old name. But it gave us something on which to start, and people have used them for distribution in factories and so on, and the idea had grown. Then people—like Mr. Hammond—went to foreign countries, and came home and said "people are all using three-phase motors there, it must be right," and so they came home and used them. Then someone in this country said "here is Mr. Hammond's station using three-phase motors, it must be right," and so it went on. But of course there were really important questions in dealing with the size of conductors and mains; and the first thing was to be sure they were dealing with rational assumptions. The question of the size of the dynamo was not very important, but the case of working was enormously important. Freedom from breakdown was far more important than efficiency in most cases. In large transmissions, the capital spent in copper was most important.

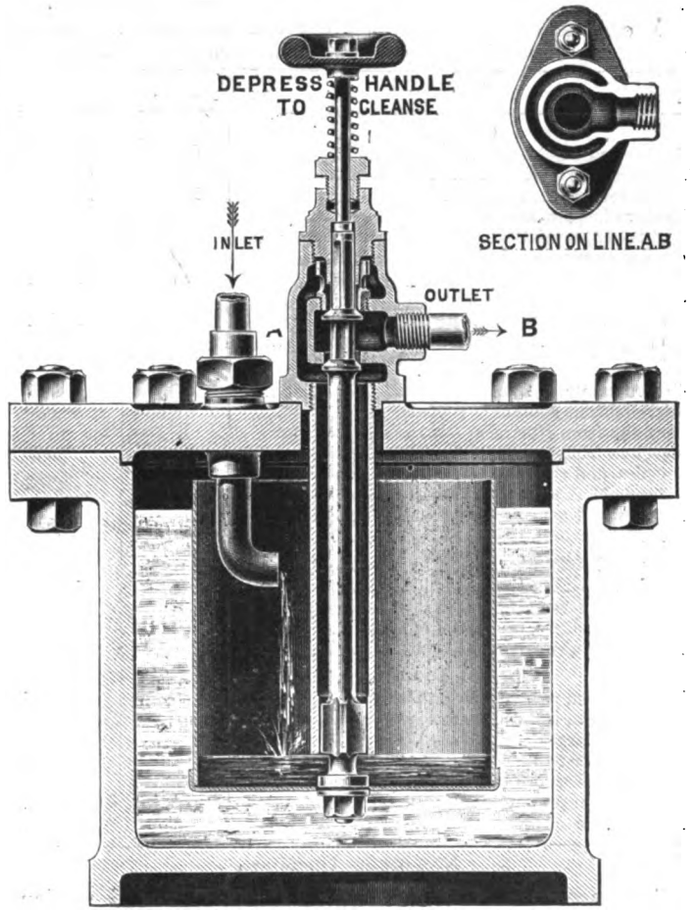
Prof. FORBES, in reply to Prof. Perry's request for more figures as to the size of phase rectifiers that must be employed for special work, said he had already disclaimed that he could act as professor, and teach the Institution as a class. Most of the members were surely competent to calculate for themselves. With regard to boosters, Prof. Perry had very aptly commenced his remarks by saying that he did not thoroughly understand, and his remarks made that still more obvious. He (Prof. Forbes) confessed his own ignorance was profound when he had traded upon the knowledge which he expected to exist about such elementary matters, and the remarks of several gentlemen had rather astonished him. He thought it was very elementary work, and that there would have been no difficulty in seeing the point. Mr. Swinburne had put the whole thing as clearly as daylight, and he need not say anything more about it. He was sure they would all feel indebted to Mr. Ferranti for his remarks, which were historical, practical, and prophetical. His remarks about the benefit of motor generators were very valuable, and should carry great weight; while he supported Mr. Ferranti in his soul-stirring words as to the future use of single phase for long distance transmissions, and would be quite willing to follow in Mr. Ferranti's steps when the question had been more fully studied. His reply to Mr. Esson was that he did not know of any booster system in actual working. With regard to the same speaker's remark that the phase rectifiers at Oerlikon were used in order to counteract the enormous drop due the self-induction of the generators, he said he thought it was generally known that manufacturers abroad in making tenders for such work proposed the adoption of such phase rectifiers to supply the so-called wattless current, and he also presumed that everybody knew that these phase rectifiers did work whether they were economical or not. He did not think there was any difference between stranded and solid wires so far as the effect he had been discussing was concerned. The great difficulty came in in the matter of skin resistance. Mr. Hammond had mentioned that since the Continent plumped for three phase, therefore three phase must be right. Although he (the speaker) was always getting tenders for three-phase plant, it did not follow in the least that three phase was the best system.

The PRESIDENT (Dr. S. P. Thompson) said that before he asked the meeting to return a formal vote of thanks to Prof. Forbes for this epoch-making Paper, he would like to say a few words on a matter which had struck him greatly. Prof. Forbes had struck a note concerning the national importance in this crisis, of electrical engineers appreciating the advantages of distribution on a large scale, a point which had been emphasised by Mr. Ferranti and others, and it was a matter which he felt very strongly at the present time—viz., these parliamentary schemes which were approaching discussion. Here was a problem that could not be faced from the small and parochial point of view, but which must be faced from the larger point of view. The last time he visited Paderno and Rheinfelden he also visited Vizzola where there was a water power station taking about 22,000 H.P. from Lake Maggiore. This was not for lighting the city of Milan, but it was to provide power for the industries in a large number of flourishing towns in that part of Lombardy, and he had been told that half the power was contracted for before a single engine had been installed in the station. With the exception of one of the towns (Legnano) included in the area of supply, he had never heard of any of them before he visited the place, but it had been explained to him that this part of the country was the Lancashire of Italy, and they were going to have their power distributed to them from one large central station: 20,000 H.P. distributed at high pressure, and by consent of the authorities there, and with legal authority from the Italian Goverment. And we had to compete in this country with those manufacturers in North Italy. Were we to be debarred by want of proper legislature from getting power from the coal fields economically and cheaply, the same as was being done at Niagara, Rheinfelden, Vizzola, and other parts of the world? If Parliament were to debar us from doing this it would be little short of a national misfortune.

A vote of thanks to Prof. Forbes was then passed.

THE TUNLEY STEAM TRAP.

The annexed illustration shows a new form of steam trap recently put on the market, and claimed to be one of the most compact and



accessible in use. The trap works on the float principle, levers and joints having been abandoned in this form of the instrument, in order to reduce the working parts to a minimum. The floating receiver is connected direct to the valve, and moves up and down with it; being balanced, the valve works independently of the steam pressure. On account of the small extent of the rubbing surfaces,

Digitized by Google

situated only at the lower end of the valve stem, which is a loose fit, the friction is very small. It will be noticed also that it is practically impossible for any steam to pass out, as the outlet is by means of a vertical tube surrounding the valve spindle, the lower end of this tube being sealed up by the water in the receiver.

The action of the trap is as follows: Water enters through the pipe shown and drops into the floating receiver, causing it to fall as soon as its buoyancy has been overcome, thus opening the valve and allowing the water to discharge until the buoyancy is restored and the valve is closed again. Any dirt is got rid of by blowing steam through the vessel by means of the hand blow-off attachment, consisting of a plunger—independent of the valve spindle—carried through a stuffing-box at the top of the valve chamber, and provided with a handle and spring for raising it again. When first setting the trap to work the body is filled with water through a removable plug in the cover. Before being sent out from the works each trap is tested to stand a hydraulic pressure of 400lb. and a live-steam pressure of 200lb. For pressures higher than 200lb. the traps are supplied to cast-steel bodies.

These traps are being manufactured by Messrs. Fletcher Bros., of Ashton-under-Lyne, Lancashire, under license from the patentees, Messrs. A. E. and J. P. Jackson.

ELECTRICITY WORKS ACCOUNTS.

County of London and Brush Provincial Electric Lighting Co. (Ltd).

Out of the total authorised capital of £800,000 this company had, up to December 31st last, expended a total of £718,195 in respect of lighting works and plant in their London districts.

The proportion of this total expended in the northern districts, or those supplied from the City-road station, was £337,822. These districts include St. Luke's and Clerkenwell, Eastern and Western Holborn, and St. Giles. The southern districts are supplied from the Wandsworth station, and include Wandsworth, Camberwell, and Southwark. The total expenditure to the above date amounted to £380,373.

In the table which follows are given the more important particulars regarding the company's operations as a whole.

Items.	1898.	1899.
CAPITAL.		
Authorised capital	£800,000	£800,000
Share capital received	589,890	600,000
Loans received	101,000	254,957
Reserve (repairs and renewals) fund	5,000	11,915
Capital appropriated to Northern Districts Orders	273,442	337,822
Capital appropriated to Southern Districts Orders	2,889,145	380,373
Capital expended in lands, buildings, &c.	10,534	10,534
Capital invested in and advanced to the Bournemouth, Poole, Dover, Richmond and Coatbridge Electric Supply Cos.	138,208	99,101
REVENUE.		
Gross revenue	13,772	56,462
Miscellaneous sources of revenue	6,655	36,619
Revenue from Northern Districts department	2,159	6,718
Revenue from Southern Districts department	4,959	9,542
Repairs and renewals paid out of depreciation fund, Northern Districts	...	1,988
Repairs and renewals paid out of depreciation fund, Southern Districts	...	1,595
EXPENDITURE OUT OF REVENUE.		
Total	6,487	11,015
Directors' fees, rents, rates, taxes, insurance, wages and proportions of salaries	3,342	6,758
Miscellaneous charges	3,145	4,257
FINANCIAL RESULTS.		
Balance from revenue account	7,285	45,417
Balance from last account	10,091	5,776
Interest charges	...	5,033
Set aside for repairs and renewals	...	6,500
Sum available for distribution	17,376	39,661
Dividend on preference shares	6 per cent.	6 per cent.
Dividend on ordinary shares	Nil	4 per cent.

NORTHERN DISTRICTS.

The accounts of the working of the City-road station, supplying the northern districts, form the subject of our first table. The figures we are able to give show that most satisfactory progress has been made by this department during the period dealt with.

The equivalent lamp connections, it will be noticed, have increased from 36,303 to 61,188 8 c.p. lamps—an advance of nearly 69 per cent. The output of 1899 indicates an increase of 106 per cent. over that of 1898.

The load factor of last year at 8·14 per cent. shows that the load was less satisfactory in character than in 1898 when the load factor was 10·5 per cent. In view of this the reduction in the costs which has taken place is the more commendable. As they are, the costs are still slightly above what they might reasonably be expected to stand at. It is the works costs—more particularly the fuel and repairs items—that are the source of the failure to make a very satisfactory cost sheet.

The average revenue received stands at the moderate figure of not quite 5d. per unit sold. Unfortunately the margin between expenditure and revenue has only permitted of a working profit of £6,718, representing 2·2 per cent. of the mean capital expenditure. This, however, compares well with the £2,347 of 1898.

It may be mentioned that the supply of current in the Western, Holborn, and St. Giles district was commenced last summer. The plant erected for the generation of continuous current for power purposes has a capacity of about 2,000 H.P.

SOUTHERN DISTRICTS.

These districts are supplied by the Wandsworth station, the accounts of which are analysed in our second table.

Here, again, excellent progress is shown in respect both of economy of working and increase of business. The lamp connections have risen 89 per cent., and the output nearly 80 per cent. In 1898 the load factor was 8·17 per cent. Last year, however, this factor had risen to 12·4 per cent.

The aggregate costs have fallen from 3d. to 2·6d. per unit. As was the case in the City-road station, the Wandsworth station costs are still somewhat too high in the circumstances, and, in fact, taking into account the outputs and load factors, there is very little to choose between the two stations in the merit of the results for 1899. The management and property charges at both stations, as given, are below the average, but since there are charges which we generally include under this head appearing in the company's general accounts, it is useless to criticise closely or comment on the management or aggregate costs of the two departments as set forth in our tables.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

CLERKENWELL.—REMARKS—* Includes the whole northern district of the company—viz., St. Luke's, Clerkenwell, Eastern and Western Holborn and St. Giles—all supplied or to be supplied from the City-road station. *a* Date of commencement of generation of electricity. *b* Includes motors aggregating 128 H.P. *c* The *total* authorised capital of the *company* is £900,000. The net revenue and capital accounts are not separately rendered from the totals referring to the whole of the company's operations. *d* Being the capital appropriated to the County of London (North) Electric Lighting Order, 1892, and Northern Extensions Order, 1897. *e* Includes £385 for station lighting and £107 general charges. *f* The engineers' salaries are included under "wages at station" and "distribution of electricity." *g* Being depreciation of meters only. *h* On maximum demand system, 7d. for first 1½ hours and 3d. after for lighting, and 6d. for first hour and 2d. after for power supply. *i* Includes £188 stores and works expenses. *j* Inclusive of £67 to insurance and £60 auditing.

WANDSWORTH.—REMARKS—* Including the parishes of Putney, Wandsworth, Tooting Graveney, Streatham and Clapham, also Camberwell and Southwark. *a* The *total* authorised capital of the *company* is £800,000. *b* The net revenue and capital accounts are not separately rendered from the total respecting the whole of the company's operations. *c* Includes £192 for station lighting and £125 general charges. *d* The engineers' salaries are included under generation and distribution charges. *e* Includes £42 to insurance and £45 to auditing. *f* Being depreciation of meters only (see note *b*). *g* For lighting, 7d. for first 1½ hours, 3d. after; for power, 6d. for first hour, 3d. after; by maximum demand system. *h* Inclusive of £114 to stores and works expenses. *i* Includes £51 to insurance and £60 to auditing.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "The Electrician" *commence in April and October.*

"The Electrician" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to* **6** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II:—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof J. A. Ewing, M.A. New edition. Price 10s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. Curtis-Hayward, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. Raphael. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By Dane Sinclair and F. C. Raphael.

SPECIAL NOTICE.

NOW READY.—Vol. XLIV. of "The Electrician" (950 pages), bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "The Electrician" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

LONG DISTANCE POWER TRANSMISSION.

Prof. George Forbes's Paper "On Distant Electric Power Transmission," recently read before the Institution of Electrical Engineers, touched on a subject of great interest and importance at the present moment, and despite the somewhat "scrappy" nature of the Paper itself, a good discussion was expected. The debate which took place, however, although not devoid of interest and entertainment, was disappointing, probably owing to the fact that proofs of the Paper were only issued to intending speakers a comparatively short time before the Paper was read, and because the reading and discussion had to be completed in one evening. We have already in a previous issue referred to the first part of the Paper, which describes briefly, and in a mannner which the author states is liable to mislead, a few of the existing examples of long-distance transmission. A letter in the correspondence columns of this issue also makes reference to this part of the Paper.

In the second part, the point to which Prof. Forbes appears to attach the greatest importance is the question of the applicability of Kelvin's law of economy in particular cases, and the possible advantages to be gained in reinforcing the voltage along the line by means of boosters. As Prof. Forbes correctly pointed out, Kelvin's law is only applicable in a special instance, and although the size of transmission lines and feeders may be chosen with due regard to similar principles, the law as it stands is not of universal application. Distributing networks have long been designed with no regard for this law, for, in the first instance, cables in accordance with it would occasion too large a drop in voltage; and, secondly, because the actual load on, and the load factor of, a supply network cannot be foreseen. This latter fact accounts for the phenomenon that not even feeders are, as a rule, calculated on a Kelvin law basis. An attempt, which can hardly be called thoroughly successful, was made in a more recent Paper before the Institution of Electrical Engineers, to calculate in the same way the size of feeders and distributors for a tramway system. In the case of many power transmission systems, however, a theoretical treatment is more likely to be useful, for it frequently happens that the amount of power to be transmitted is accurately known at the time the scheme is designed; yet, although we have no objection "to see an accurate volume published on the correct use and

Digitized by Google

development of KELVIN'S laws of economy," as Prof. FORBES desires, we should side with Mr. SWINBURNE in not desiring to read it unless its practical bearing was evident. The booster system described in the Paper was, we were sorry to see, criticised rather too impetuously by Prof. PERRY. Given the problem to transmit electrical power at a stated pressure with a maximum percentage loss, it is evident that by keeping up the pressure from one end of the line to the other an efficiency lower than 50 per cent. can be obtained. There cannot be a doubt, however, that this case is one that would rarely occur in practice. It requires really only a cursory examination of the accounts published by electricity supply undertakings to reveal the fact that fuel is but one of many items in works costs and but a comparatively small proportion of the total costs. It might, therefore, be thought at first sight that the employment of twice as much fuel would often pay, if thereby a large capital expenditure in mains were saved—and there are, of course, many instances in the colonies and abroad where the actual water power costs nothing or practically nothing. But all, or nearly all, the items in the works costs are more or less proportional to the number of units generated, and the capital charges which go to make up the total costs vary with the kilowatt capacity of the plant, which would, of course, have to be augmented if the loss of energy in transmission were doubled. Thus the cost of the extra waste of energy which has to be taken account of when the cross-section of the conductor is reduced, *plus* the interest and depreciation on the cost of the line boosters for keeping up the pressure, has to be set against the saving in interest and depreciation in the conductors; and it is probable that this extreme measure of increasing the loss to over 50 per cent. would only be resorted to in practice in rare instances of transmission over extremely long distances, and for the most part in schemes whose realisation is also far distant. Possibly that was Prof. FORBES' meaning in choosing as the title of his Paper "On Distant Electric Power Transmission," instead of "On Electric Power Transmission over Long Distances."

The question of two-phase versus three-phase, or, in view of Mr. FERRANTI'S speech, the triangular conflict between single, two, and three phase, has not yet been settled, nor will it be settled merely by the drawing of triangles and stars and placing $\sqrt{2}$ and $\sqrt{3}$ along their sides. Prof. FORBES rightly states that the relative amount of copper in the two instances depends upon the conventional definition of the pressure employed, and assumes, to prove his case, the convention that the pressure to be taken in the comparison is the pressure between each conductor and earth. In this country, however, the Board of Trade kindly undertakes the task of defining such conventions, and deems that, "the expression 'pressure' means the difference of electrical potential between any two conductors through which a supply of energy is given, or between any part of either conductor and the earth," implying naturally that the greater of these two is to be assumed in applying the regulations. Moreover, we believe that the Board of Trade has laid down, up to the present, that one of the conductors themselves is to be earthed at one point, a condition which would upset the balance of both of Prof. FORBES' diagrams in his Fig. 4. When it comes to the laying of the underground cables, moreover, the cost of insulation and the effect of capacity complicate the problem, and there is also the advisability or otherwise of a common return on a two-phase system to be considered. It is a pity that those who could speak from experience on these and similar matters were silent or not present at the Institution the other evening; and failing that, it was to be regretted that none of those present who had had the opportunity of viewing two or three-phase plants, and discussing their features with the designers, were able to add something to the discussion of pros and cons. That Mr. HAMMOND had travelled a considerable distance on the Continent in a week, and found that continental engineers "plumped for three-phase" was interesting, but if in his travels Mr. HAMMOND discovered the reason for the latter fact he did not disclose it.

Probably remembering that the meeting hall of the Institution was "not a class room," Prof. FORBES did not trouble to be accurate with regard to the employment of aluminium for underground cables. The increase in the cost of insulation on a cable varies approximately with the diameter in the case of thick cables with the small radial thickness of insulation suitable for comparatively low pressures, but, for the general case, it varies more nearly with the expression $(da + a^2)$, where d is the diameter of the conductor and a the dielectric thickness. For high pressures the second term in the expression may be more important than the first, so that a point may be reached when aluminium is economical for underground mains.

It remains to mention one important—in fact, the most important—feature in the discussion, namely, the expressions of opinion, notably by Mr. FERRANTI and Prof. S. P. THOMPSON on the attitude that electrical engineers should take up with regard to the power bills now before Parliament. We entered fully into this aspect of these power bills in our last two issues, and it is greatly to be regretted that several of the local authorities opposing the bills should be supported by electrical engineers connected with the Institution of Electrical Engineers, and, at the same time, men more or less prominent in their profession. We quote Mr. FERRANTI: "There ought to be sufficient patriotism, honour, and good feeling in this country among a great profession like ours to fight for that profession and for the advancement of science in this country."

A CENTURY OF CHEMISTRY AT THE ROYAL INSTITUTION.

(*Continued from page 96.*)

LECTURE III.

The third lecture of this course was delivered by Prof. Dewar, F.R.S., on Thursday, May 10, at the Royal Institution. He concluded his account of the important work which Davy carried out while still at the Royal Institution by references to his investigations on the nature of the diamond, and his experimental proof that it was merely a form of carbon, showing that the CO_2 produced by its combustion contained no trace of any other substance. The lecturer proved the same result in a different manner. A small diamond was strongly heated in a blowpipe flame, and when red-hot was dropped into a bath of liquid air, when solid carbonic acid was formed. Another important investigation of Davy's, carried out in consequence of his being consulted by the Admiralty, led to his advising that the copper sheathing of ships, which ordinarily underwent very rapid corrosion, should have applied to them small areas of another metal (Zn), which would be more rapidly attacked than the copper. While this remedy was effectual in preserving the copper sheaths, it was found that the bottoms of the ships became fouler than before, owing to the fact that the clean copper surface afforded a valuable situation for the growth of barnacles, shell-fish, &c.

The lecturer next referred briefly to Brande, who was connected with the Institution for over 50 years, and who occupied himself mainly in that branch of chemistry which lies just on the border-land of chemistry and physiology. Coming next to the work of Faraday, Prof. Dewar remarked that while his early chemical investigations were not

Digitized by Google

very diffuse, they were remarkable for the experience in manipulation which they gave him, and for the nature and great variety of the subjects investigated by him. He made analyses of the chalks, and also investigated some properties of gases, such as transpiration, occlusion, &c. He examined also some properties of steel, and optical glasses, as a direct result of which investigations he produced palladium steel, and heavy glass. The latter substance has never been excelled as a solid insulating material, and is still extensively used in the laboratory. It is almost perfectly non-hygroscopic, and while ordinary glass very readily discharges an electrometer, "heavy glass" is not able to do so. About this time Faraday, acting with Davy, repeated Oersted's famous experiments on the mutual action of a current and magnet, and it was with the galvanometer which this discovery gave birth to, that Faraday continued the electro-chemical investigations of Davy, proving the relation between the gas formed in a water voltameter and the current acting, and also discovering the laws of electrolysis of metallic-salt solutions. Faraday's experiments proved, directly, that the cations deposited were proportional to the atomic weight of the metal; and Helmholtz, lecturing in the Royal Institution about 20 years ago, asserted that Faraday's experiments proved the atomic nature of electricity. Prof. Dewar observed that the property of electro-chemical equivalence, for the discovery of which we are entirely indebted to Faraday, was now used in defining our standard of current, and also assisted the chemist in checking the value of the atomic weight of any substance, found by some other method, although for chemical reasons it was not generally applicable.

Faraday also made experiments to discover whether there were any limits to the evaporation of liquids. He found that a surface of mercury, contained in a space which was cooled down to the lowest temperature then attainable, evaporated sufficiently to amalgamate a gold leaf suspended above it. For these experiments Faraday increased his vacuum by a method previously employed by Davy, viz., to cool intensely the vacuum space by such cooling agents as were then known. The effectiveness of this treatment in procuring the desired result was illustrated by Prof. Dewar by immersing a Geissler tube in liquid air, and passing an electric discharge through it, the changes in the nature of the discharge as the temperature is being lowered pointing to the high vacuum which this method will give. The lecture concluded with some remarks on the liquefaction of gases, in which branch of science Faraday was a pioneer.

(*To be concluded.*)

SOFTENED POSITIVE ACCUMULATOR PLATES.

It has often been noticed that, after a certain number of discharges, the active material of a peroxide positive plate becomes soft on the surface, and that this softening gradually extends inwards until it leads to the destruction of the paste. Dr. F. Peters, who was unable to find any explanation of the effect in the literature relating to secondary batteries, has made a number of experiments to determine its cause. From these he has obtained the following results, which he publishes in the *Centralblatt für Accumulatoren und Elementenkunde* in the hope that an exchange of views with other experimenters may lead to a satisfactory solution of the problem. His first experiments were made to ascertain whether the chemical composition of the surface layers of the old plates which had become soft was the same as that of new plates with a healthy surface. Samples were taken from the surface and the middle layers of the plates, and thoroughly washed to free them from sulphuric acid, and it was found that it made no difference to the results obtained whether the washing was done with hot or cold water. The samples were air-dried, and then the amounts of active oxygen and peroxide of lead which they contained were estimated by means of oxalic acid and permanganate of potash. The total amount of lead was determined by dissolving the substance in nitric acid and hydrogen peroxide, any excess of the latter being removed by electrolysis. The small difference which was observed between the amount of active oxygen and peroxide found in the normal plates and that in the softened one may be accidental, especially as the softened electrodes had stood longer without charge before the experiment than the normal ones. On comparing the amount of active oxygen and peroxide in the positive active material in the samples from the middle, with those from the surface, one sees from the following tables that it is approximately the same in the normal substance, but is considerably more in the middle than at the surface in the softened plates.

Soft Plates.

—	Surface washed with cold water.	Surface washed with hot water.	Middle.
1. Percentage of active oxygen	2·99 (Mean of 3 best.)	3·03 (Mean of 3 best.)	4·53 (Mean of 3 best.)
2. Percentage of lead peroxide (determined directly)	44·63 (Mean of 3 best.)	45·33 (Mean of 3 best.)	67·69 (Mean of 3 best.)
3. Percentage of lead peroxide (calculated from 4 and 5)	44·26	...	67·23
4. Percentage of lead oxide corresponding to the whole lead mass (including that present as peroxide	81·14 (Mean of 2 best.)	...	87·48 Mean of 2 best.)
5. Percentage of lead oxide corresponding to the quantity of lead present in the active mass as lead oxide	39·81 (Mean of 3 best.)	...	24·75 (Mean of 3 best.)
6. Percentage loss of oxygen and water on ignition	3·60 (Mean of 3 best.)	3·54	5·26 (Mean of 3 best.)
7. Percentage of water (calculated from 6 and 1)	0·61	0·51	0·73

Normal Plates.

1. Percentage of active oxygen	3·34 (Mean of 3 best.)	3·10 (Mean of 3 best.)	3·39 (Mean of 3 best.)
2. Percentage of lead peroxide (determined directly	48·04 (Mean of 3 best.)	47·59 (Mean of 3 best.)	53·67 (Mean of 3 best.)
3. Percentage of lead peroxide (calculated from 4 and 5)	48·75	...	53·65
4. Percentage of lead oxide corresponding to the whole mass (including that present as peroxide)	93·05	...	93·94
5. Percentage of lead oxide corresponding to the quantity of lead present in the active mass as lead oxide	47·57 (Mean of 3 best.)	49·73	43·88 (Mean of 3 best.)
6. Percentage loss of oxygen and water on ignition	4·19 (Mean of 3 best.)	4·18	4·61 (Mean of 2 best.)
7. Percentage of water (calculated from 6 and 1)	0·85	1·08	1·02

These differences cannot be ascribed to unequal formation, as this was the same for both sets of plates. The formation of the lead peroxide goes on at the same rate at the middle of the plate as it does on its surface, because in the former position the conducting supports of the plate are nearer together, while, in the case of the plates which become softened the loosening of the filling material has taken place owing to the constantly repeated expansion and contraction caused by charge and discharge. In the middle the loosened particles are kept in good contact with the supports by the layer of active material above them, and, owing to the greater porosity of the material, the transformation of a greater quantity of lead into lead peroxide becomes possible. But the particles of the surface layers which were first acted on become loosened from each other and from the supports, an action which is accelerated by the bubbles of oxygen formed. In consequence of this want of contact the conversion of lead into peroxide does not proceed as rapidly on the surface as in the inner layers of the plate, and as the loosened portions of the paste are more easily saturated by the acid they form a soft mass on the surface of the plate, and as fresh layers of the plate become softened the action penetrates deeper until the whole is softened.

If this explanation is correct, it ought to be possible to restore a plate with softened surface to its original hard condition, and experiments show that this can be done by discharging the plate and charging it up again in the reverse direction, which causes it to contract, thus restoring the contact between the particles of the plate and the supports, while the plate remains porous. A small portion of the surface material falls off in this process; but on again reversing the current and charging the plates in the original direction, the expansion of the particles fills up the pores left between them, so that the firmness and coherence of the active material is restored.

An experiment was made to ascertain if the discharge of the normal hard positive plate took place as readily as that of the softened one. Two cells were taken, similar in all respects except that one contained a softened, and the other a hard positive plate. The electrolyte consisted of sulphuric acid, 24°B., and they were both charged up for 12 hours with a current of 2·5 amperes before commencement of the actual experiment. The initial E.M.F. of the

Digitized by Google

cell with the softened plate was 2·06 volts, and it yielded 17·2 ampere hours, whilst its potential difference fell from 2·002 volts to 0 volt, and it took 14·5 ampere hours for the potential difference to fall to 1·8 volts. The cell with the normal hard positive plate showed an E.M.F. of 2·043 volts and it gave a discharge of 20·8 ampere hours, whilst the potential difference fell from 2·000 volts to zero; but the potential difference of 1·8 volts was reached in 13·5 ampere hours, so that although the total capacity of cell was greater by 3·6 ampere hours, or 21 per cent., its useful capacity was 1 ampere hour less. But after the potential difference had fallen to 1·8 volts, its fall was much more rapid in the case of the softened plate than in that of the hard plate, because during discharge the contact between the active material and the supports was improving in the case of the softened plates.

The resistance of the active material on the two plates was found to be practically identical, the method employed being to wash the active material, dry it, and then compress it under equal pressure into columns of the same height in glass tubes of equal diameter.

CORRESPONDENCE.

HIGH VOLTAGE TRANSMISSION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the report of Prof. Forbes' paper on Long Distance Transmission, printed in *The Electrician* of May 4, the following paragraph occurs in reference to the Paderno plant (p. 50): "The only other plant in the world which can be compared in this feature (*i.e.*, high generated pressure) with Paderno is the transmission by the General Electric Co., U.S.A., from Mechanicsville to Schenectady, where both generator and motor are used at 10,000 volts without the intervention of any transformer."

Prof. Forbes must surely have overlooked the 20,000 H.P. Chambly-Montreal plant. The generators at Chambly are 2,000 kw., two-phase S.K.C. inductor machines, producing a pressure across each independent phase of 12,000 volts.

The writer was employed by the Royal Electric Co., of Montreal, by whom they were built, on much of the testing of these machines, and has therefore a fairly intimate knowledge of them.—Yours, &c., C. H. DOUGLAS.

Hargrave Vicarage, Chester, May 10.

EXTENDED POLE-PIECES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Under the title of "Johnson-Lundell Electric Traction Plant" (*The Electrician*, Vol. XLIV., p. 922), is given a description of a Lundell generator, the supposed novel feature of which consists in extending the field pole in the direction of revolution, so as to throw the gap between two consecutive field poles forward, instead of having it, as usual, midway between the field poles, and the field poles are also given slots which virtually divide the poles into two.

I would call attention to the fact that the extension of the field poles forward in the direction of revolution in generators is very old, as is evident by an inspection of the United States patent to E. J. Houston and E. Thomson, entitled "Dynamo Electric Machines," No. 219,157, and dated Sept. 2, 1879. There is also a corresponding British patent, the number and date of which I do not have at present for reference.

The expedient of dividing the field poles by slots, so as to make one or more sections of the field pole, is also quite old, as those who are familiar with the development of the art must know. Moreover, it is an expedient of very doubtful utility. I do not think it has any other effect than to increase the general reluctance of the field pole.—Yours, &c.,

Lynn, Mass., May 1. ELIHU THOMSON.

Verband Deutscher Elektrotechniker.—The annual meeting of this association will take place at Kiel from June 17th to 20th, and on this occasion it has been decided to add to the attractions a small exhibition of electrical novelties chiefly of interest in naval circles. A local committee has been formed for this purpose, with Herr Sartori as president.

LEGAL INTELLIGENCE.

Chamberlain and Hookham v. the Corporation of Bradford.

The first two days' hearing of this case were reported in our last issue, pp. 99 to 104, and abstracts of the important patents and articles referred to were also given. On Thursday, last week, the case was continued, when

Mr. JAMES SWINBURNE, cross-examined by Mr. CRIPPS, said the plaintiffs' machine consisted of two parts, the motor and the brake. He thought that, as to the motor, the substantial difficulty at the time was practically the question of friction.

Now, as regards getting rid of friction, do you suggest that defendants took anything from the plaintiffs' specification?—No, I think defendants got round the difficulty in another way.

Cross-examined as to the brake, WITNESS said the magnets must be constant. Constancy could be retained in a magnet in different ways. It could be obtained, if you used proper steel, by artificial ageing, and that was known before Mr. Hookham's specification.

Therefore, if anyone obtained constancy in a magnet by artificial ageing that would not be infringement or interference with plaintiffs' specification?—No, I think not.

Now I think the other point with regard to the magnet was to get it strong?—Yes.

Supposing you had a magnet made constant by artificial ageing and used two or three weaker magnets instead of one powerful magnet, would you say that would be interference with the plaintiffs' specification?—That would be a question of degree.

He was aware that the defendants formerly used three magnets and now used two. He thought that after the plaintiff brought out his specification any other person would, in future, be prevented from using a strong constant magnet on the disc brake of the meter.

So fas as power is concerned, do you really say that after the plaintiffs' specification no one is to use the common form of horse-shoe magnet?—Well, it is very difficult to say. There is a distinction between knowing how to do a thing and knowing how to do it without infringing.

I will put aside the question of artificial ageing for the present. Do you say that magnets of the ordinary horse-shoe kind are not to be used after the plaintiffs' specification?—That is a very broad question. Magnets like that had been used before the plaintiffs' specification, but not used on a meter. The question of ageing might be hypothetical.

Do you say that no one could use a magnet of that form and shape after the plaintiffs' specification for any purpose?—Of course it could be used for some purposes.

It was a known form of magnet?—Yes, there were lots and lots of magnets used with the 70 rule.

In reply to a question put by his lordship the previous day, WITNESS handed up the Electric Lighting Act, which he pointed out laid down that the variation of pressure in any consumer's terminal should not exceed 4 per cent. from the declared constant pressure.

In further cross-examination, WITNESS said the ageing of magnets to produce constancy was well known. In a report on Hookham's meter, made about 1892, he said, talking of the magnets, that "the field is made up of a bundle of bars of steel of a special character, properly hardened, with cast-iron pole pieces"—that was an accurate description of Hookham's magnets.

That would not be in any sense a description of the magnets which defendants use?—No; they now use cast-iron pole pieces.

Nor is there a bundle of bars of steel of a special character?—No, I believe there is a bar only.

Mr. FLETCHER MOULTON pointed out that the meter upon which the report was made could not be the one in the specification.

WITNESS said where the magnetic circuit was closed you had constancy and permanency, and the nearer you got to that, the smaller the extent to which you had broken the circuit, the greater would be the permanency and constancy. In Siemens' energy measurer* there was a brake by a fan revolving in a liquid. As regards the motor, Siemens' and Hookham's systems were practically the same. Marcel Deprez suggested the use of a copper disc revolving between the limits of a permanent magnet.

Mr. CRIPPS: All that defendants have done in modification of Siemens is to attach a copper disc revolving between the limbs of a permanent magnet?—Yes.

And the law of it, I think, was correctly stated below?—Yes.

Do you say, after that statement by Marcel Deprez, that the defendants ought to be prevented, in connection with a meter like Siemens', from introducing a copper disc revolving between the limbs of a permanent magnet?—It depends on whether you use Hookham's invention in so doing.

What is there to prevent the defendants from taking what Siemens and Deprez tells them in the year 1884?—Nothing.

Mr. Justice FARWELL: For my information tell me if you had had that put before you in 1884 could you have made a meter?—I do not know that I could have made a satisfactory thing. I might have gone in that direction, and might have discovered how to make a permanent magnet. The result of following those directions would be that you would have a thing with insufficient brake power.

Why? You can get a constant magnet by artifically ageing it. Do you mean to say there would be any objection to putting on three or four magnets if one was not strong enough?—No, I think you could put on a good many magnets, but I doubt if you could get on enough unless you knew how to make this special magnet.

Do you say defendant's magnet is aged or made according to anything in Hookham's specification?—No, I conclude from its working so efficiently that it is made from Hookham's specification.

* *See* p. 103 of the last issue of *The Electrician*.

Digitized by Google

Mr. CRIPPS: Your Lordship will hear evidence on that point.

In further cross-examination WITNESS said Deprez's references on this point were to his magnetic-speed indicator.* Abel's magnet and the defendants' magnet were practically the same shape. If four of Abel's magnets were attached side by side it would be practically the same thing; there might, perhaps, be a little more permanency and power in Abel's.

An instrument was handed to Witness which was described as following Siemens for the motor, with a copper disc for the brake according to M. Deprez, and a form of magnet found in Deprez's figure of a speed indicator. WITNESS said he had little doubt it would work perfectly as an energy meter; how accurate it would be, and how long it would work accurately, he did not know.

I put it to you, supposing we follow what was pointed out by Siemens and Deprez years before Hookman, you do not suggest that we are not entitled to do that?—That is a matter of law.

Mr. Justice FARWELL: Is there any practical reason why an instrument made according to their anterior suggestions should not work?

Mr. CRIPPS: It does work.

Mr. Justice FARWELL: That he does not know.

WITNESS: This, I think, would certainly work as a meter now. Whether the magnet would be permanent I do not know without trial. If this meter had been brought out in 1887 I think you could have sold it.

Mr. CRIPPS: But the question of constancy or permanency is dealt with by ageing the magnets. Supposing you found one aged magnet was not sufficient, why not put on two or three?—If you put six aged magnets on, I should think it was quite possible it would work commercially. If a magnet was going to change it generally developed rapidly.

An ammeter of Ayrton and Perry's was handed up, which was stated to have been constructed about 18 years. In a measuring instrument for amperes, the WITNESS agreed they had in this exhibit what was a constant magnet in the right sense, and it had not varied for 18 years.

You can hardly get a more apt illustration of prior user as regards what either plaintiffs or defendants had done?—As regards constancy it is very good.

As regards power, if one magnet is not sufficient, why not put on four?—You can use as many as you like.

The WITNESS did not agree that a constant field produced according to Hookham's specification could not be used in connection with the measuring of alternating currents. It would not, however, be a good practical arrangement, and, so far as he knew, had not ever been done.

Questioned as to Handford's specification,† WITNESS stated that they had there described a constant field produced by permanent steel magnets. In Handford's patent one got a motor working in a constant field. The method of producing a constant field by saturation was known before plaintiffs' patent. It was known in measuring instruments, and was shown by Weston.

Re-examined by Mr. MOULTON: There were many thousands of specifications relating to electrical measuring instruments before 1887, and there were many thousands of papers relating to magnets and magnetism before that date. When one knew how to do a thing it was not difficult to look up literature and pick here and there and put things together to show how to make it, but in many cases to do that thoroughly was difficult. At that time there were hundreds of forms of magnets used. He (witness) thought you could get any form of magnet you wanted. Since the plaintiffs' specification it was known that power and permanence were not naturally exclusive. He thought that a permanent magnet such as Mr. Hookham referred to was perfectly constant and very powerful. In instruments that existed before the date of this specification constancy was sufficient without power, and power without constancy. There was nothing he could think of before the date of this specification which communicated the union of the two. In the case of a meter, if you did not have constancy it failed of its purpose. Strength was important for accuracy in a meter. Meters had very peculiar requirements.

Prior to the Hookham specification, do you know of anything which published to the world the way to get permanent magnets constant and strong?—No, I think the electrical world is indebted to Mr. Hookham for the way to make strong permanent magnets. This was one of the things wanted in order to make practical this type of meter, which was then theoretically known. There was nothing in the d'Arsonval galvanometer which would tell the world how to make an effective meter. Too much strength was a disadvantage there, and quite weak magnets were used.

Questioned as to a specification of Siemens, he said that Siemens was trying to obtain magneto-currents for telegraphic work, and constancy was not in the least necessary for that purpose. In Siemens' instrument the paraffin or liquid was intended to fill the whole apparatus. That would not be a practical or accurate measuring instrument. Viscosity of the liquid would vary with temperature. M. Deprez did not convert Siemens to his brake. Prior to Hookham, he found no suggestion that his type of magnet should be selected for the purposes of a magnetic drag. Weston was a well-known electrician, who devoted a great deal of attention to measuring instruments. His meter, so styled, was a wholly impractical instrument. In Abel, the active part consisted of two little pole-pieces embracing the mercury. In Jamin, again, the active part was the ends, not the sides. A practical meter must start, if possible, with one lamp. In order to improve the speed indicator Deprez gave a suggestion that would make it impracticable for the use of a meter. Plaintiffs' meter was mainly described in the specification for direct currents, but it was indicated that it could be used for alternating purposes. Defendants' meter would also work with alternating currents. The principle of Hookham's meter was that it was made on the straight-line law with a brake following the straight-line law. Weston's (No. 2) meter would not measure anything. As to the commutator, if constructed as Hookham described it, it was an instrument for accurate work.

Mr. DUGALD CLERK, examined by Mr. A. J. WALTER, said he was of opinion that Mr. Hookham's invention was the first practical meter which showed a simple mode of motor and a simple mode of brake. That was to say, a motor in which the twisting power was proportional to the current, and in which the resistance of the brake was proportional to the speed of rotation of the brake. He found for the first time a magnetic brake working in such a way as to give a powerful field as well as a constant field. In obtaining a practical meter to start with one lamp, it was necessary to have a strong field. That was pointed out by Hookham in his specification. The constancy of the brake was also important, and that the brake should have a long range. He had visited Bradford and, in company with the chief engineer to the Bradford Corporation, examined the system of electrical distribution.

What practically is the condition of the potential in the mains at Bradford?—They work at 230 volts nominal potential in the main, and the variation, from what I saw, does not exceed 2 per cent. I also examined the meter used in the Bradford circuits.

Is there in that meter any device for the purpose of starting the meter?—Yes, there is a separate small coil.

Is that the device pointed out in Hookham's specification—the winding round the magnets or armature for the purpose of starting?—Yes.

He had read through all the specifications introduced into the case, none of which, in his opinion, disclosed to the world the inventions contained in Hookham's specification. Siemens' suggestions for a motor-meter contained no provisions for eliminating the friction. M. Deprez had found no indication of the importance of (1) a powerful field, (2) a constant field for the brake, (3) a strong field for the brake, (4) provisions against friction.

Are those conditions which you do not find in Deprez's Paper of importance or not in the construction of a practical meter?—Of great importance.

In respect of claim 3 of the plaintiffs' specification, WITNESS found an infringement in the use of large pole pieces closely approaching each other.

In your view of the plaintiffs' specification, looking at it as an engineer, do you see any emphasis placed on independent pole pieces?—The "poles" described in the specification were additional poles, and were shown in the drawings as additional poles, but in that there was no limitation as to the poles being attached separately. This was a simple and convenient method of making them.

Cross-examined by Mr. GRAHAM: Ayrton and Perry failed in showing any practical details to enable any person to make an electricity meter. One of the great advantages of Hookham's specification was making the frictional force very small compared with other forces. Everybody agreed that that was what was wanted, but none of them could do it. Hookham did it by making a very powerful magnet and a very powerful brake, and thus reduced his friction. A powerful brake diminished the friction. Hookham made his magnet powerful, he supposed, by sending a large discharge round the wires which magnetised his magnets. There was nothing new in that. It was well known how to make a magnet powerful. Hookham obtained constancy by having large pole pieces closely fronting each other, and by this method of large pole pieces and close fronting he completed his magnetic circuit and kept it constant.

Had that not been pointed out before the date of Hookham's patent?—Not that I am aware of.

Mr. WALTER then read the *verbatim* report of the judgment of Mr. Justice Wills in the action tried in the Queen's Bench Division—Chamberlain and Hookham *v.* Johnson and Phillips—delivered some three years ago,* when the learned judge upheld the validity of the plaintiffs' patent.

That closed the plaintiffs' case.

In opening the case for the defendants:—

Mr. CRIPPS said there were one or two points it was desirable he should deal with at this stage. As regarded the judgment of Mr. Justice Wills, just read, there the conditions and circumstances were entirely different from those in this case, and the specific issues raised in that action were totally distinct from the issues raised in this action. Although it might be necessary in a certain event hereafter to raise the question of validity of plaintiffs' patent by reason of anticipation, he could not now ask his Lordship to disagree with Mr. Justice Wills's finding. But when new anticipations were put before his Lordship which were not before Mr. Justice Wills that was not entirely a question of construction, but a new issue, with which his Lordship could deal. It was impossible to patent a principle in English law. It was undoubtedly law that if anyone took those same old principles and placed them in a different way and produced a different result he was not infringing, and that was the defendants' case. The merit of the defendants' machine, and the use made of it, was that it measured energy. He could not see the weight of Mr. Moulton's argument upon that part of the case. You had to compare machine with machine, and if anyone liked to use a particular machine under conditions in which one of the factors was the same, that did not matter. Defendants' machine was a machine which measured energy. It was a machine which was different in its results, and was arrived at by an entirely different combination to what was found in the plaintiffs' specification. Defendants' combination was absolutely different and distinct from the plaintiffs', and aimed at a different object. Mr. Swinburne had said that the merit of the invention was so far as it got rid of friction in the motor part of the invention. Ayrton and Perry, in their energy meter, did not manage to get rid of friction, and so did not arrive at practical results, whereas Chamberlain and Hookham did. Mr. Hookham had explained that defendants used not one of those methods adopted by the plaintiffs. In Hookham's machine were a constant field and particular methods of getting rid of friction. Up to this point, he submitted, there could be no

Digitized by Google

infringement. So far as defendants were concerned, a constant field was destructive. Another point remained—that of the brake, which had to be constant and effective. The two methods to which Chamberlain and Hookham directed attention were constancy and power. They described a particular form of magnetic application of a magnet to a brake which was not suggested to be new. What was new was the particular way in which plaintiffs arrived at a magnet which was constant and effective. That was only one part of the combination; but what the defendants did was not in contradiction of any claim made by Chamberlain and Hookham's specification at all. What defendants did was this: they got a magnet made in steel of a special form, and then artificially aged it in order to make it constant. That was common knowledge at the time, and there was nothing about it in Chamberlain and Hookham. This process of artificially ageing the magnet reduced its power by something like 15 per cent. So far there was no suggestion of contravention of plaintiffs' claims. It was said by plaintiffs that they showed the way of making magnets both constant and powerful. What was the answer to that? Defendants' magnet followed the horse-shoe form familiar to any schoolboy, somewhat modified no doubt. As regards strength and separation of the poles it was merely a matter of degree. They made it permanent by artificially ageing it. It was said that there was difficulty in getting a magnet both powerful and constant. That would not, in fact, be a difficulty as regards the defendants. For power, at one time they had used three magnets; now they used two. The form of their magnet entirely differed from plaintiffs'. It was obvious that so far as the magnet was concerned there could in no sense be said to be infringement, because supposing they took the poles a little nearer, or used five or six magnets to get the proper power, it was only a question of degree. In the same way it was well known that you could apply a permanent magnet to a copper disc in order to get brake power. It could not be claimed by Chamberlain and Hookham that they invented this. Although there was a mention of alternating currents by plaintiffs, there was no suggestion of applying the Hookham meter to alternating currents. No less a proportion than 90 per cent. of defendants' meters were used for alternating currents. Defendants' meter was the practical meter of everyday life, in use all over the world, and there were thousands of them in use in England. In the Hookham specification there were no directions or description whatever to enable alternating currents to be produced. There were 1,000,000 of the Thomson meters in use, and 90 per cent. of them had been applied to alternating currents. Therefore, upon that no question could arise regarding alternating currents whatever else his lordship might think the defendants had infringed. Nor was there any question that the defendants had infringed the plaintiff's armature. The next point was with regard to the commutator. So far as that was concerned, the defendants used a system absolutely distinct from what was suggested in Chamberlain and Hookham's patent. That patent said, "to avoid the friction of a brush." Now, the defendants used a brush, and got rid of the friction in an entirely different way from Chamberlain and Hookham. In plaintiffs' meter there were the mercury cisterns. In defendants' there was the silver. In the one there was the vertical arrangement, in the other the horizontal. Both got rid of the friction. In his evidence. Mr. Hookham himself admitted that defendants' commutator was materially different from his own. In fact, defendants' solution of the difficulty of friction was absolutely different from the description in the specification of Hookham's patent. The defendants did not employ mercury in any way. With regard to the point of constancy and power, what was charged against the defendants was that plaintiffs in their combination did use a magnet for braking purposes which was both constant and powerful, and the merit, or the claimed merit, of it was in the combination of constancy and power. Constancy could, of course, be obtained by ageing. So far as power was concerned. The greater the power you had on the magnet the slower were the revolutions of your meter. The advantage of that was in altering the measuring power of your instrument. In the one case the meter revolved more quickly than in the other, and wore out more quickly. There was no principle involved in that. It was merely a question of degree.

His LORDSHIP said he thought Mr. Swinburne said that, before Hookham, constancy and power were mutually distracting, and were co-existent.

Mr. CRIPPS said he thought that the effect of Mr. Swinburne's evidence was that constancy and power were well known in every sense, and what Mr. Hookham really did—he must be given every credit for this—was to invent, according to Mr. Justice Wills, a form of permanent magnet. Mr. Justice Wills, however, had never found that every magnet which happened to have constancy—of course, every magnet had some, as ageing was well known—was an infringement of what the plaintiffs did. It was only a question of degree. The defendants had constancy, and small power was sufficient for them. He supposed you could not have a magnet without power, and a magnet which must have power must have constancy. What Mr. Hookham did was to describe a particular form of magnet in which he had both constancy and power. It would really be incredible and impossible to say that no constant magnet was to be used by anyone except Mr. Hookham, because every magnet had some power.

His LORDSHIP: You say the idea of combining constancy and power was not patentable. You say you use an entirely different kind of magnet, and that you are entitled to do so.

Mr. CRIPPS agreed. He contended that plaintiffs were in a peculiarly weak position as inventors. All the principles were thoroughly ascertained and known, and the most they could claim was the particular form of application. Bearing in mind what he had said that power here was only a matter of degree whether the brake spun a little faster or a little slower, they got just the same recording instrument by either one or the other. Then Mr. Hookham said in his specification that for small installations he "preferred" a number of small magnets—bar magnets substituted for the large magnets in the drawing. There they had Mr. Hookham saying—very properly—that in place of electro-magnets he "preferred" a particular form of magnet, that form being a number of bars with artificial iron holdings. When that was done—that was to say, after this arrangement of bars and poles had been built up, the permanent magnet was practically constant. But that was not the essence of Hookham's invention at all, but merely a direction of a preferable way of carrying it out. The claim in the plaintiffs' specification was first, "An electricity meter for measuring currents, consisting of an electro-motor with constant field, arranged substantially as hereinbefore described and illustrated in the accompanying drawings, the said electro-motor being combined with an electric brake also moving in a constant or nearly constant field, preferably the same field as that in which the armature rotates substantially as herein described." Now, that was quite distinct from the defendants' meter, which was a meter for measuring energy, and which was absolutely distinct as a machine, and also distinct as to all the mechanical agencies employed. The plaintiffs' claim said, "An electro-motor with constant field." The defendants did not do that; it would be absolutely destructive to them. And then the plaintiff said, "Arranged as hereinbefore described." Well, but the defendants' whole arrangement was absolutely distinct in every feature from the plaintiffs so far as the motor was concerned. It was quite clear to his (Mr. Cripps') mind with regard to this first claim that there was no infringement. The defendants' arrangement was a different arrangement, applied differently, and for a different object. Then the third claim which was relied upon was this:—"In electricity meters, the use for the purpose of procuring a powerful and constant magnetic field of permanent magnets arranged as described, with very large polar surfaces closely fronting each other, so as to form a narrow slit, in which the disc armature revolves whether the same be magnetised in position or otherwise, and the means described for regulating the same when or if necessary, substantially as herein described and in part illustrated in the accompanying drawings." Mr. Moulton had carefully confined himself to only reading that claim, without making any comment upon it. That claim, however, did not carry the matter any further than the first claim, and everything therefore turned upon the first. The others were subsidiary incidents of the first. As to the disc armature, the defendants were outside that. The claim was for a disc armature—a powerful and constant magnetic field for the disc armature of the meter. In defendants' machine a disc armature was not the motor, and there was no constant field at all. So they came to the magnet point, which seemed to him to be the litigious point between the parties. On that point material evidence had been given in this court which had not been before Mr. Justice Wills at all, and he (Mr. Cripps) thought the evidence here given was absolutely conclusive on the point of infringement. Mr. Justice Wills found that the plaintiffs' specification contained all the theory on which Mr. Hookham based his invention, and that it had not been done before. But here, in this case, the defendants had shown that it had not only been previously disclosed in principle, but had been practically carried out before Hookham's specification appeared at all. If he (Mr. Cripps) could point out that what Hookham did by his patent had both in theory and practice, been previously disclosed, then what became of the suggested invention? It was clear that Marcel Deprez knew the theory. So far as the brake was concerned it was nothing but a question of degree. It merely meant whether the copper plate ran slower or faster. Those which ran the quicker wore out the quicker. Learned counsel submitted that these things were well known, and that the defendants were entitled to take advantage of public knowledge. He next referred to the magnet, which he said defendants had induced Prof. Ayrton to take out of an ampere-measuring meter made 18 years ago. This magnet he said had been in use for 18 years—long before Chamberlain and Hookham's specification—and had been perfectly constant for 18 years. As regards strength, it was, as he was informed, a great deal stronger than the magnet which defendants used. Prof. Ayrton had tested that magnet, which had been in use for 18 years, and found it was constant and more powerful than the magnet which defendants used. The answer therefore was, that there was no question of theory. Could it then be said that it was infringement for defendants to use a magnet of that constancy and power? Constancy could be obtained by a well-known method, and as regards the combination of constancy and power it was merely a question of degree. He would not trouble his Lordship with Ayrton and Perry's specification, because it was admitted on all hands that they disclosed the whole theory. He must take Mr. Justice Wills' judgment that they did not go beyond the whole theory. The difficulty Ayrton and Perry had to contend with was the friction theory. The learned counsel next referred to Abel's specification of 1884. He said that there was really no difference, in form between the magnet there and the one used by the defendants, as Mr. Swinburne had said if three or four of those magnets had been put side by side they got the defendants' exactly. There was also claim 5, which was—"The construction and arrangement of parts forming a commutator, making contact by means of mercury placed in insulated vessels, the axis of revolution of the commutator being vertical, substantially as hereinbefore described." He would not dwell on that now, but he mentioned it because it was a point that might be raised hereafter on the question of validity. But to sum up his argument, he would say this. He would not say it was admitted, but there was no serious dispute that the defendants' machine or combination was quite distinct from that of the plaintiffs'. It was for energy in one case and for current in the other. It was admitted also—or not seriously disputed—that the claim of the plaintiffs was entirely based on a law known at the time, and was for a combination carrying out what was then a well-known law. So far, again, as motor power was concerned, the machines were distinct. The real difficulty felt at the time was as to friction; and, so far as mechanical means for getting rid of the difficulty of friction was concerned those of defendants were entirely different from those of plaintiffs, and the

Digitized by Google

theory of getting rid of it had been disclosed in an article published before the date of the plaintiffs' patent. As to the brake, the only matter claimed by Mr. Hookham was constancy and power, and Mr. Swinburne had told the court that both were matters of degree. So far as constancy was concerned defendants used a method well known before Hookham's; and so far as power was concerned, it did not matter whether one magnet was of a certain power as compared with another. Defendants used a magnet distinct in form and power from that of plaintiffs; defendants used simply the ordinary common form of magnet; and viewing all the facts, he submitted that there was no substantial kind of infringement here at all.

Evidence for the defendants was then taken.

Mr. S. Z. DE FERRANTI, examined by Mr. Cripps, said he was one of the first electricians to deal with the question of meters, his first attempt to make one being in 1882. He succeeded in his attempt at the end of 1883 or beginning of 1884. He then produced a continuous-current meter, and it had been very largely used since then.

It has been suggested that Mr. Hookham first solved the difficulty of measuring currents by meter. Is that so?—No. I saw his specification directly it was printed, and I thought at the time that it described a very inferior instrument to the one I had already produced. That might sound egotistical, but I did think that the patent was a retrogade step.

Continuing, WITNESS said the sale of electrical meters came into commercial use in the latter part of 1886. Very little was done before that date. There was no real commercial demand for electrical meters before 1888. The meter produced (one of Ferranti's) was made in 1884 and shown at work at one of the South Kensington exhibitions on a lighting circuit. It was found in practice that the meter would start with a single candle lamp, and measured up to 20 lamps with very fair accuracy. The business in these meters had rapidly increased, and at the present time there were perhaps 40,000 of these current meters being used in England of that pattern, but not of that particular shape. It was not really until 1888 or 1889 that electric lighting had made any advance in England. The defendants' meter was an energy meter. An energy meter was entirely distinct from a current meter, and was totally different. In a current meter you must have one element constant, viz., the field or armature. In the defendants' meter it was not necessary to have a constant field in connection with the motor. To have constancy in an energy motor would be destructive. He was acquainted with the arrangement of Mr. Hookham's meter with regard to friction. He thought it was a bad arrangement, and did not succeed in getting a low friction. He did not find any similar method of dealing with the friction in defendants' meter. The commutator in plaintiffs' meter was distinct from anything he found in defendants' meter. It was one of the elements which he considered unsatisfactory in plaintiffs' meter, and which was satisfactory and proved to be good in defendants'. Defendants' form of commutator was a very special form. The commutator was a very important factor in producing an effective meter. Before the Chamberlain and Hookham patent it was known how to make a magnet constant. In his view the question of friction was most vital. It was most necessary to get a meter to start readily with a small amount of load upon, and for this you must have low friction. There was nothing new in getting constancy. There were several processes of getting constancy of magnets known as ageing. Ageing reduced the power of the magnet perhaps some 15 per cent. For the purposes of the brake it was necessary, besides constancy, that the magnet should be powerful, so as to prevent the meter running too fast and so wearing itself out. Supposing defendants had a weaker brake to what they used, they would get a measuring instrument which would wear out faster. There was no difference in the principle whatever; it was only a matter of speed. It was a commercial element only, and did not affect the electrical law. He had made himself acquainted with the special form of magnet in the Chamberlain and Hookham machine. In defendants' machine a common form of magnet was used. In defendants' machine one could put in as many of those magnets as were wanted—two or four, or any number necessary to get the best speed for their meter and brakes. It was merely a commercial question. There was no difference between the motor part of Siemens' instrument* and defendants', except that the latter had got the silver commutator. Otherwise it was exactly the same. He had read the Deprez article.* That article, also, stated the general law on the subject with perfect accuracy. There was no difference between what he found described in Siemens' and Deprez's article and defendants' meter. It was at the commencement of the period of running that a meter would lose force; but if he found one going constant for six months then he knew that it had real constancy. He should have had no difficulty in producing an energy meter such as was used by defendants from the descriptions in these articles. Mr. Uppenborn also, in his article, showed that he had a perfectly complete and clear understanding of the whole subject.

Supposing you were dealing with the question of a powerful motor, you obtain it by plaintiffs' specification by means of a strong permanent magnet with a constant field?—Yes, and in defendants' you get it by another way. You get a permanent magnet in a constant field. The motor in defendants' meter is made of two parts—the armature and the field. The field in defendants' is a magnetic field in air and is formed simply by the passage of an electric current. No iron or steel is used in either the field or the armature in defendants' meter. In fact, the two machines are absolutely different things.

When the hearing was resumed on Monday, as Mr. Ferranti had been unavoidably detained, his cross-examination was deferred, and Mr. CRIPPS, for the defence, called

Prof. J. A. EWING, who said he had made himself acquainted with the meter used by defendants and had carefully studied plaintiffs' specification, and could not say that defendants' meter infringed the specification in any way. The specification was for a meter to measure electric currents, and defendants' meter was an energy meter. In order to get a current meter it was necessary to design the arrangements so as to secure a constant field for the motor. The variation was vital and essential. The energy meter could be used for all sorts of purposes. So far as there were special mechanical methods for dealing with the question of friction, defendants' machine was not an infringement of plaintiffs'. There was no resemblance between them. For instance, the commutator in defendants' machine was quite different from that described in plaintiffs' specification. Defendants used a form of commutator which was known for many years before the date of plaintiffs' specification. It was known how to get constancy before that date. Defendants' magnet in no way infringed that described in plaintiffs' specification. It was absolutely different. The use of a permanent magnet to create power was well-known before the date of the specification. After the article which was written by M. Deprez, which was very clear, an electrician with a knowledge of his subject could easily have made such a meter as that used by defendants. The power they wanted on the motors was the driving power, and they wanted a powerful motive power to reduce friction, so as to make the friction a negligible quantity. So far as driving power and motor were concerned, those of defendants' and plaintiffs' were quite distinct. A description given by Faraday of a magnet in his "Experimental Researches in Electricity" might be construed as describing something very similar to the magnet set forth in plaintiffs' specification. In order to get constancy they wanted a magnet which should be as nearly as possible a closed magnetic circuit so as to reduce the loss of power; but there were other conditions equally important. There was nothing in defendants' magnet which was not compatible with what had been known and described prior to plaintiffs' specification. Witness was shown a magnet which had been constant for 18 years, and said that, as compared with it, there was nothing different in plaintiffs' specification. There was a difference in the building up; but the principle was the same, and had been known for some years before. There was no basis for the suggestion that at the time Mr. Hookham made his experiments permanent magnets had been practically abandoned for the purposes for which compensation was required. They were in actual use. In Ayrton and Perry's specification of 1882*, there were described the principles of the law which was contained in Chamberlain and Hookham. It was common knowledge, and there would be then no difficulty in getting a magnet constant and of sufficient power. He had read in plaintiffs' specification the description of what had been called in this case the vertical commutator, but that idea was not novel. Witness was shown two models of earlier instruments than plaintiffs' specification, and said that each had a vertical commutator such as was described in plaintiffs' specification. Taking the words "disc armature," *per se*, in the specification, he, as an electrician, would at once understand that the words meant the armature of the motor. Witness pointed out that in the specification Mr. Hookham said that the armature consisted of so and so, the commutator consisted of so and so, and the brake consisted of so and so.

Cross-examined by Mr. Moulton: Defendants were actual users of their machine. In his specification, plaintiff stipulated for a constant field, or as an alternative an armature of steady power.

By his description in the specification it is plain that plaintiff intended to use the same connections on his magnet as you find in defendants'?—I think that is so.

The specification says that the electromotor might be of any of the ordinary kinds then in use. At that time there were alternating-current motors?—Yes.

And they were made exactly as in Siemens' meter or defendants' meter?—Yes.

Continuing, Prof. EWING said: Defendants' meter measured energy, and never measured anything else but energy. Not one particle of the general principle of defendants' meter was applicable to an alternating-current meter. He could point to many passages in specifications, &c., prior to the Hookham specification for getting constancy and power in permanent magnets. Witness cited Elphinstone and Vincent, Siemens, Faraday, Jamin, Deprez, D'Arsonval, and Ayrton. D'Arsonval's reference was a Paper on electric telephones with concentric poles. It referred to the shape of magnets which were found to give good results in speaking on telephone lines. One pole was in the shape of a ring, with the other pole coming up in the centre, both on the same side of the telephone plate.

How in the world could these instructions tell the world the right way to get a good magnet for your brake?—They showed the form of magnet which gave good results for whatever purposes they were used.

Is there any suggestion here that the magnet was constant or powerful?—Well, it gives good results.

I put it to you that the words "increases the effect" refer to the giving a clearer sound?—That might be so.

May I put it to you, that of all the things least of importance in a telephone, constancy is one?—Of course constancy is not of nearly so much importance in a telephone as in a meter.

Questioned with regard to Jamin's references to Magnets†, WITNESS could not agree that Jamin's work was merely directed to increase the portative power of magnets. Jamin spoke of an instrument in which constancy was important. He could not say whether Faraday, in the passage referred to above in his "Experimental Researches," was talking about bar or horseshoe magnets. He thought the whole of what Faraday said was applicable to magnets of all forms.

Prior to 1887, had you ever seen one of the specifications cited in this case?—Prior to 1887 I was not much interested in specifications, but I certainly had seen some of Marcel Deprez's writings.

Can you say you have seen one of these other publications?—Yes; I have no doubt that I read Faraday. I had certainly seen extracts from Jamin, but I had not read all his papers.

Digitized by Google

I ask you about the actual passages cited here. With the exception of Faraday, can you say you had seen any one of these passages cited in this case?—I cannot at this date specifically refer to any of those passages as having been seen by me before, but I may say this there was nothing contained in those passages I was not acquainted with.

He had not suggested that ageing took out something like 15 per cent. He did not think it ever had the reputation of taking out the larger part of the magnetism. It would all depend upon the kind of steel used.

It does not take more money to make a good magnet than a bad one, if you choose the right form, does it?—Well, the process of ageing is, I think, one of cost—you have to pay more for good than for bad magnet steel. Defendants' was a cheap magnet so far as geometrical form was concerned.

Questioned further, WITNESS said: Abel's instrument was a current indicator. He had never seen an Abel meter. He thought the invention was practically the same as that by M. Lipmann which witness had seen.

Re-examined by Mr. Cripps: The saturation of an electrical magnet was in all cases a question of degree. No electromotor with constant field could be used for measuring alternating currents.

If you wanted a meter for alternating current could you use the same field both for the motor and the brake?—No, it is quite impossible.

Do you know within what range of power defendants use their magnets on different meters?—I am told it varies as much as 50 per cent. I have noticed there are wide variations in the power of the magnets they use.

Further re-examined, WITNESS stated he considered that from the directions given in the Paper of 1884 on "Siemens Energy Meter" any competent workman could have actually made the meter.

Prof. W. E. AYRTON, examined by Mr. Graham, said he had devoted a good deal of attention to the question of the constancy of magnets, which really depended in the first instance, and to a very important degree, on the chemical composition of the steel; secondly, it depended very materially on artificial ageing; lastly, but to a much smaller extent, it depended upon the geometrical form into which the magnet was made. At the date of the Hookham patent he knew how to make, and had made, a constant and powerful magnet. He had studied the manufacture of defendants' magnets in common with Prof. Elihu Thomson, at the General Electric Co.'s works in Lynn, Mass., U.S.A., where they were made in large numbers. The magnets were made out of steel heated to a dull red heat. Then there was a very special form of ageing. They were dipped 26 times successively into boiling water and into cold water, the operation occupying 13 hours. A large number of magnets were hung on a kind of chain arrangement which was kept rotating continuously. That was how the magnets were made constant. Prior to ageing, the magnets were made powerful. Defendants used a very injurious device to magnetise their magnets. It was not the fact that at the date of Hookham's specification, permanent magnets had been abandoned where absolute constancy was required. Mr. Hookham did not teach the world for the first time how to make a powerful and constant magnet. He did not teach the world how to make either a constant magnet or a powerful magnet, or the two combined. He (witness) knew how to do it years before Hookham's specification was lodged.

Referring to the Ayrton and Perry specification of 1882, WITNESS stated that the only thing which prevented them from making a successful commercial meter was their not knowing how to make the armature and brushes with sufficiently small friction. The difficulty of getting a constant and powerful magnet did not stand in their way. He was in Court when Prof. Ewing was examined, and agreed with him that Hookham's specification gave no directions how to make a satisfactory alternating current meter. He did not think that an intelligent workman could have made a successful alternating-current meter after reading Hookham's specification.

Cross-examined by Mr. Moulton, WITNESS said that the plaintiffs' meter consisted of an electric motor with constant field. It was not a sufficient description, in his opinion, to say it consisted of an electric motor and brake.

It has those two parts in it?—Yes; with an addition which is vital—the constant field. Electric motors, both for direct currents and alternating currents were both known. If it were wanted to have an electric motor with alternating currents you must have the alternating current both in your field and in your armature. He hoped every electrician would know that. Supposing you wanted to get an electric meter for alternating current a permanent magnet could not be used. In plaintiffs' meter the mercury commutator did not work. He found, for example, that by putting a little mercury into the clip he changed the reading by 15 per cent. There was no indication on the meter how much mercury to put in.

On Tuesday Prof. AYRTON was further cross-examined by Mr. Walter. WITNESS said that defendants' magnet was reduced in power by two processes, but still it was a strong magnet.

Mr. Justice FARWELL: Is there any definition of "strong" in connection with electricity?—There is no definition of strong. There might be 900 lines or 1,000 lines. They were both powerful. But the term strong was only relative to something else with which it was compared. Defendants' was a magnet which had not a third of the braking force of his (witness's) 16 years old magnet.

Mr. WALTER: You have spoken to this effect—that for the purpose of braking you prefer concentrated poles?—Yes.

Concentration at the expense of magnetism is a disadvantage?—I do not know what you mean by concentration there.

I ask you to assume that concentration can only be attained by the loss of magnetism. The widening of the poles then would be an advantage?—It is not so. Assuming what you state—which I must qualify as not being true—then it would be a mistake to have concentration, because constancy is of great importance; but my own experiments show that you can get concentration and constancy.

With a strong magnet?—Yes

Continuing, WITNESS said Dredge, in his book,* showed how to make a Siemens armature to work with a mercury commutator. The model before him showed how to use the pools of mercury higher in the middle than at their sides.

Re-examined by Mr. Cripps, WITNESS said defendants' magnet was of a form well known to him before the date of plaintiffs' specification. There was no reference in plaintiffs' specification to the use of silver for the purposes of a commutator. Defendants' meter was merely the Siemens meter with the Deprez addition, and with silver used in the commutator, no reference to which appeared in plaintiffs' specification.

Mr. S. Z. DE FERRANTI was then re-called. In answer to Mr. Cripps he said that in plaintiffs' specification the meter described would not work at all with alternating currents. He did not think the thing could have been understood when it was written.

Cross-examined by Mr. Walter, WITNESS said that in 1887 it was not generally known how to make alternating-current motors, but present knowledge showed that, with the then existing descriptions of instruments, they could have made instruments which would have worked with alternating currents.

You have spoken about the constancy of permanent magnets. Before the date of Hookham's specification, what do you say as regards what was known of the constancy of permanent magnets combined with strength? As I gather, what had been done was to expose the magnets to some of the conditions to which they would be exposed in use—such as temperature—until they got down to the condition in which, when in use, normal circumstances would not affect them?—Yes, they were subjected to conditions whereby, when put in practical use, they would not be affected by similar conditions afterwards. The silver brushes were very important, and more durable and certain than copper ones. The meter would work for a short time with copper or brass brushes, however. He allowed that he himself was an inventor, yet he did not say he could have invented Hookham's meter at the time; but, speaking from knowledge common at the time of the specification, the instrument could have been made. The information others had given left nothing to the imagination. Deprez, Uppenborn and others had fully described the theory and how to carry it out in every detail for a commercial meter. There was no suggestion as to making the brushes with silver which, witness considered, added to the life of the meter, but otherwise the knowledge before the specification was sufficient.

Re-examined by Mr. Cripps, WITNESS said that both the theory and practice of the instrument were set forth by Deprez most completely. Siemens would have worked for a long time with copper brushes, but silver was better. It was a refinement of practice. Plaintiffs' commutator was intended to be an improvement in practice, but it had not proved so. Witness would not measure alternating currents by an arrangement consisting of an electro-motor with constant field. The arrangement in the specification was, in his opinion, entirely wrong. The difficulty of the Hookham meter as an alternating current meter was that the magnet proposed did not vary at the same time as the current in the armature. This was quite a complex electrical matter to anybody but a technical person, but if anybody tried to construct an alternating current meter on the lines shown by Mr. Hookham he would get something which was utterly and hopelessly wrong.

Prof. SILVANUS P. THOMPSON was then examined by Mr. Bousfield as to the construction of a meter according to the plaintiffs' specification, and answered a few questions put by Mr. Walter in cross-examination.

This closed the evidence in the case, and Mr. BOUSFIELD addressed the Court on behalf of the defendants. He first recalled the fundamental difference between a current meter and an energy meter, and then said that the difference between this case and that before Mr. Justice Wills† was this. In the case before Mr. Justice Wills defendants had the current meter. They had a meter with a permanent electro-magnet built up with pole pieces at the ends; and the armature was of the plate type, so that they had the arrangement which Hookham had described in his specification as using a disc or cup at once as a motor and a brake. They had, therefore, absolutely the identical elements which made a current meter—a constant field with an armature developing force proportional to the current The defendants had not in that case the Siemens meter. They had infringed with a current meter. But in the present case the defendants had an energy meter identical with Siemens. The substantial points which differentiated the two instruments were these. In the plaintiffs' they had first a constant field; next, special arrangements for minimising friction; and third, strong power in order to reduce friction. Every witness, he thought, agreed that the difficulty of overcoming friction was the real practical difficulty at the time. Hookham made his driving-force very large and the friction consequently very small. In defendants' meter, so far from having constant field, theirs was a field one component of which varied with the current, and the other component varied with the electromotive force; and their method of reducing friction was now very different from that of the plaintiffs'. Mr. Justice Wills had treated permanent magnets in the case before him as if they were not an essential of the first claim, which only dealt with the constant field.

Mr. Justice FARWELL: Mr. Moulton puts it forward that what you have done is a breach of claims 1 and 3, and Mr. Justice Wills said it was a combination of all the elements.

Mr. BOUSFIELD thought that Mr. Justice Wills did not mean that. When he said it was a combination, he was referring to the combination in the first claim, and he went on to say that he had come to the conclusion that there was substantial identity—in other words, that a case of infringement of the first claim was made out, but on the sixth claim—improvement in pole pieces—Mr. Justice Wills found that defendants had not

Digitized by Google

infringed. Therefore combination of all the elements of the whole of the claims could not have been meant. And as to claim 3, that was a claim for something less than the whole thing which was claimed in claim 1. But having regard to the fact that that third claim dealt with something not in the provisional specification at all, he (Mr. Bousfield) submitted that it was a claim which could only be infringed if one used a motor such as was substantially described in claim 1. He submitted that if defendants did not infringe claim 1 they could not infringe claim 3. Claim 3 was only a detail in the working out of the invention in claim 1. Plaintiffs had a magnet with big ends in order to get a powerful motive force; and defendants had a very different arrangement, for although they also obtained a powerful driving force they had no iron, and they relied on two coils—the coil which carried the current and the inner coil. The difficulty of getting over the question of friction was met by defendants also in a very different way from the arrangement adopted by plaintiffs. Their defence with regard to infringement might be summed up in the broadest way in saying the plaintiffs' was a patent for a current meter and defendants' was an energy meter. Defendants also said that they did not infringe, even if his Lordship took his learned friend's point about its being used in a constant circuit so as to be a current meter. Even if his learned friend was right about that, still he (Mr. Bousfield) should say it was not an electro-motor substantially as described, because it had a constant field. It had not got an arrangement for giving a powerful driving force and for minimisingfriction, which were really the features which governed the construction in plaintiffs' specification so far as the motor was concerned. Up to a certain point defendants' was accurate as an energy meter, but after that point it ceased to be a meter at all. Counsel next referred to the third claim, and the question of infringement on that head—the disc armature. He said that really this claim was never intended to cover either the use of permanent magnets for the motor or for the motor and brake combined. The case actually illustrated was the motor and brake combined—one disc. The claim had no application for magnets used solely for braking purposes. Of course this was an additional point to the other points.

His LORDSHIP: I thought you did not take this magnet?

Mr. BOUSFIELD said that was so, but a great many points were raised about that, and it was necessary to deal with them all. He submitted that the claim in question was never intended to apply to the use of constant and powerful magnets in connection with the brake, but only in conjunction with the disc armature. Referring to the magnets, counsel said it could not possibly be said defendants used the form of electro-magnets invented by Mr. Hookham. Defendants' principle was to let the magnets down to such a point as to make them sufficiently constant. That was to say defendants got their constancy in the old way, and got the requisite power, not by any special construction of magnet, but by having two magnets, or if necessary three or more. He contended that although Mr. Hookham mentioned an alternating meter in his specification, he excluded it in his claim. Referring to the alleged anticipations of plaintiffs' patent by Siemens and Deprez, so far as the principle of constancy and power in the magnet was concerned, defendants' point on that was that they were following the line laid down by Siemens. If plaintiffs said their specification excluded the defendants', the plaintiffs destroyed their own specification, because what defendants did was like Siemens.

Mr. FLETCHER MOULTON, in replying on the whole case, said he began the case by stating that plaintiffs accused defendants (the Bradford Corporation) of using a meter in which there was a constant field, and in which permanent magnets used for the brake were powerful and constant according to that which plaintiffs claimed in claim 3. The difference between his learned friends and himself as to the third claim was one very much more of law than of fact. So far as fact went his learned friends had never met the evidence of Mr. Dugald Clerk that the circuit on which this was to be put was a circuit of practically constant potential and the consequence of that was that the armature in this case was practically of constant strength. Defendants said their instrument was designed to measure energy and not to measure current, and even that when they used it under circumstances where, in fact, it measured current, it could not come within plaintiffs' patent. But he would say, further, that plaintiffs' instrument was constructed on purpose to be used under circumstances such as those of the Bradford Corporation. There was a device mentioned in plaintiffs' patent which they did not claim, because someone else had done it before, and that was the starting coil. That was a coil which would destroy the serviceability of a meter if it were put on any circuit of higher electromotive force. Plaintiffs worked their meter in a constant field and got it by permanent magnets. Supposing that Bradford worked their meters in a constant field, they might get it from any source. If they kept their mains constant, the field was constant, and they had not denied it, and so they had been taking a convenient source for a constant field. But how did a field obtained from those mains differ from one obtained from secondary batteries? Bradford had used it as a constant field, and therefore had used the meter as a current meter; and with regard to the third claim, the Bradford people had obtained their effective brake by means of magnets of the type described in plaintiffs' third claim. The case against plaintiffs was one of invalidity and non-infringement, and neither had been substantiated. In fact, in spite of three or four more years of searching for fresh material, the present case was substantially the same as that which was tried before Mr. Justice Wills. So far as invention went, the combination of arrangement in plaintiffs' specification was novel and had not been published to the world in any way by anything which had been put before the Court now of date prior to Mr. Hookham's specification. Half a dozen people might have worked at the idea of trying to get a meter and failed, but the plaintiffs had succeeded, and the fact that the magnets used by plaintiffs had been used for other purposes did not tell the world that they were suitable for the purposes of meters. What defendants had done here was, with present later knowledge, to take hints from Deprez that they could not have appreciated at the date of the publication of Deprez's Paper. Dealing with the alleged anticipations, counsel, referring to Marcel Deprez, said his paper was purely theoretical and did not carry the matter further than Ayrton and Perry except that he simply pointed out that fluid friction would not do. There was not a hint in Marcel Deprez to anybody that magnets of any particular form should be used. There was merely a general statement and reference to the magnetic speed indicator, or only a reference to the law of the current. Dealing with Siemens' specification, Mr. Moulton said Siemens put his commutator at the ends of his magnets, which were neither permanent nor powerful, and he had got a wrong idea of the law. Siemens was practically at the head of the electrical world at this date, and it was important to point out that he never saw the importance of these matters. Counsel said he did not think it necessary to deal with the other alleged anticipations, because it was idle to suggest that because a man found a magnet of a particular form, which worked well in a telephone, that that told the world how to make the brake of a thing which had got to work accurately and to measure quantity. Plaintiffs' specification, counsel claimed, was the first working out of a practical meter rendered practical by two things—viz., a frictionless motor and a powerful and constant field. Mr. Hookham claimed the procuring of a powerful and constant magnetic field by permanent magnets arranged as described, with the large polar surfaces closely fronting each other. He (Mr. Moulton) could find no anticipation of this method of the application of magnets of that kind to electricity meters in the papers before his Lordship. The question of the magnets being built up was not really the question in the case. The plaintiffs said, to succeed you must have an extraordinary form of magnet, and without it you could not succeed. If that was so, and Mr. Hookham told the world how to succeed, that was a useful invention. Mr. Moulton submitted that defendants had clearly infringed plaintiffs' third claim. In Abel's magnet there was no suggestion how strongly he magnetised, and nobody suggested that Abel's magnet was used with the large polar surfaces having the function of plaintiffs' polar surfaces. There was nothing in Abel's specification to show that his magnets would be suitable for the brake of a meter. And there was no other magnet which counsel knew of which was like the magnet plaintiffs described. Magnets like the one of Prof. Ayrton had been produced. As Prof. Ayrton's magnet existed, it would not be within plaintiffs' description. What Prof. Ayrton did was to add something to it in the course of the case, so as to bring up one of the poles very close to the other. Supposing he produced a good field by such a magnet plaintiffs had no opportunity of testing the magnet or its permanency, or anything of the kind. That magnet was not what defendants used. Defendants' magnet had got those flat pieces brought up very near to one another, and he submitted it came within the words, "Large polar surfaces closely fronting each other, so as to form a narrow slit in which the brake revolves." He, therefore, contended that defendants had infringed plaintiffs' third claim.

At the conclusion of Mr. Moulton's address on Wednesday, his Lordship said he would give judgment as soon as possible.

Judgment was accordingly reserved.

Castner-Kellner Alkali Co. (Ltd.) v. Commercial Development Corporation (Ltd.).

On Tuesday, the House of Lords, consisting of the Lord Chancellor (Lord Halsbury) and Lords Macnaghten, Morris, Shand and Brampton, heard the arguments in this Appeal by the plaintiffs from an order of the Court of Appeal discharging a judgment of Mr. Justice Bigham. The action was brought to restrain infringement of a patent for an improved electrolytic apparatus for producing caustic soda or caustic potash from suitable salts by a continuous electrical process. The defendants denied infringement and alleged that the patent was invalid on the ground that the invention was neither new, useful nor subject matter for letters patent; and also that the complete specification described and claimed inventions not comprised within the provisional specification. Mr. Justice Bigham decided in favour of the plaintiffs, holding that there was sufficient invention to form subject matter for letters patent, that there was no disconformity, and that the defendants had infringed. He accordingly granted the plaintiffs a perpetual injunction. By a majority the Court of Appeal reversed that decision, the Master of the Rolls (Lord Lindley) and Lord Justice Rigby holding that the patent was invalid on the ground of disconformity, and Lord Justice Rigby adding that in his opinion the patent was invalid also for want of subject matter, while Lord Justice Vaughan Williams though the patent was valid and had been infringed. From that decision the plaintiffs now appealed.

On Oct. 23, 1894 a patent (No. 20,259 of 1894) was granted to Carl Kellner, of Vienna, for "Improvements in electrolytic apparatus for decomposing metallic salts."

The COMPLETE SPECIFICATION was as follows:—

"This invention has reference to an apparatus for the electrolysis of alkaline salts with the aid of a stationary mercury cathode, in which the amalgam formed by electrolytic action has its location changed from the decomposing chamber, in which it is produced, to a combining chamber, in which it is decomposed and the cation combined with water, an acid, or other body, by the shifting of a partition which is adapted to be moved to and fro in the mercury and serves to separate the two aforesaid chambers from each other. The partition is in this case made in the form of a bell closed at its lower edge by a mercury seal and enclosing the decomposing chamber, so that the amalgam formed in the latter is caused by the shifting of the bell to have its location alternately on one side and on the other side of the bell without itself changing or moving its position, and is thus caused to gain access to and become situated in the combining chamber, whilst the mercury on the other side of the

Digitized by Google

partition, which was previously situated in the combining chamber, effects in the decomposing chamber the amalgamation of the metal that is being separated by the electrolytic decomposition of the electrolyte. In this way, a considerable output can be obtained from the apparatus with a comparatively small quantity of mercury, because both operations can take place simultaneously and uninterruptedly. In the drawings filed with my provisional specification, Fig. 1 is a vertical section taken through one cell of an apparatus constructed according to this invention; Fig. 2 is a longitudinal section, to a smaller scale, taken through the whole apparatus; Fig. 3 is a horizontal section on the line y—y of Fig. 2; and Figs. 4 and 5 are sections through the bell showing two different forms of construction of the latter. In the accompanying drawings, Fig. 6 is a longitudinal vertical section illustrating a modified construction of the apparatus shown in Fig. 2. Fig. 7 is a vertical section, and Fig. 8, a horizontal section, taken in different planes, showing a further modified construction of the said apparatus Fig. 9 is a vertical section through a cell of the apparatus, similar to that shown in Fig. 1, but provided with a short-circuited secondary electrode for the purpose of rapidly removing the alkaline metal from the amalgam that has been formed. The apparatus shown in Figs. 1, 2 and 3 comprises a vessel A for the reception of the electrolyte to be decomposed, and a trough B inserted or suspended in the vessel A, this trough having in its bottom openings b which are surrounded by projecting borders b^1 that serve to prevent the escape, through the said openings, of the layer of mercury C which serves as a cathode and covers the bottom of the trough. The anodes D are arranged in the electrolytic space of the vessel A, horizontally or vertically, and in the latter case may, as shown, also project through the openings b into the trough B. Each of the trough openings is covered over by a bell E of non-conducting material, such, for example, as glass, stoneware, porcelain, or ebonite, which dips at its lower free edge into the mercury, and is of greater width than the opening b, so that it can be moved to and fro through a certain distance over this opening, the extent of this movement being limited by the upwardly projecting border b^1. The bell thus encloses the decomposing chamber communicating with the vessel A, and forms an electrically non-conducting partition between the decomposing chamber and the combining chamber of the trough B, which is charged above the mercury cathode C, which constitutes the seal, with water, acid or other substance with which it is desired to cause the cation, previously taken up by the mercury cathode, to combine. In order that the mercury shall not become displaced by the lower end of the bell E sliding over the bottom of the trough B when the bell is being moved, slots or notches e or b^2 are provided respectively in the lower edge of the bell (as in Figs. 1 and 4), or in the bottom of the trough, as in Fig. 5. A gas exit pipe F leads from the decomposing chamber to the exterior of the vessel A. The anode D and the mercury cathode C are connected to the terminals of a suitable source of electricity. In an apparatus of large size, such as is intended to be employed on an industrial scale, the whole of the bells E are preferably united to form a cover which is provided with partitions and is adapted to be moved to and fro in the trough B, the spaces E^1 between every two bells being arranged to communicate by means of lateral openings with the trough B, as shown by Fig. 2. The gas exit pipes F are then arranged in such a manner that the generated gas is led through all the bells in succession and is drawn off from the last bell. The manner of working the apparatus is as follows:—The electrolyte, for instance, a solution of common salt, within the vessel A and the decomposing spaces or chambers becomes decomposed by the electrolytic action which takes places under the bells E, the liberated chlorine gas being led off through the pipe F, whilst the metallic sodium forms an amalgam with the mercury cathode C, which is situated within the bells E on one side of the anodes D, viz, on the right hand side in Fig. 1. If now the bells be shifted to the left, into the position shown in dotted lines in Fig. 1, the stationary mercury cathode together with amalgam becomes thereby situated in the combining chamber of the trough B which is charged, it may be for instance, with water. The sodium separates out from the amalgam and combines with the water to form sodic hydrate. At the same time, by the shifting of the bells, that portion of the mercury which was previously situated outside the left hand side portions of the bells, that is to say, in the combining chamber, will now be located in the decomposing chamber, and acts as the cathode to again produce an amalgam with the sodium which is continually being separated in the said decomposing chamber. If the bells, after a suitable interval of time, be shifted back into the position shown in full lines, *i.e.*, to the right hand, the mercury on the left hand side of the anodes, together with the amalgam formed thereon, again becomes situated in the combining chamber of the trough, and consequently within the sphere of action of the water in such chamber, whilst on the other hand the mercury situated on the right hand side of the anodes, and the amalgam portion of which has been acted upon in the meantime by water to remove the sodium therefrom, becomes again situated in the decomposing chambers for the purpose of forming fresh amalgam. It will thus be seen that by the to and fro movement of the bells, the transposition of the amalgam formed in the decomposing chambers to the combining chamber, and the practically continuous formation of caustic soda in the latter, are caused to take place alternately on the one side and on the other side of the anodes, whilst the mercury cathode itself remains at rest."

[The provisional specification was verbatim, the same as the complete specification, down to this point except that in the place of "in the drawing filed with my provisional specification," it read "in the accompanying drawings," and it did not contain a reference to, or drawing of, Figs. 6, 7, 8 and 9.]

"It is obvious that the arrangement of apparatus hereinbefore described can be modified by causing the generation of chlorine to take place outside, and the decomposition of the amalgam to take place inside the bells E. In this case, the decomposing and forming chambers are merely interchanged. Fig. 6 illustrates a construction of apparatus of this kind, in which the vessel A contains the mercury cathode C and the solution of common salt to be decomposed, whilst the bells E, that dip in the mercury, are charged with water, with which the sodium that becomes separated from the amalgam on the shifting of the bells, combines to form sodic hydrate. The vessel A is provided with a cover, A^1, that is adapted to close gas-tight, and from which leads a pipe, F, that serves to carry off the chlorine gas generated in the said vessel. The cover is provided at a suitable place with an opening which is closed by means of a movable cover, A^2, that preferably dips into a sealing liquid for the purpose of making a gas-tight joint at this part. Through the cover A^2 there passes a pipe H, which serves for discharging the hydrogen that forms in the bells E, and is supplied to the pipe H by connecting pipes H^1. The bells are rigidly connected together, and, as in the previous case, are so arranged that they can be moved to and fro in the vessel A, this movement being shared by the pipe H and the sliding cover A^2. The positive terminal wire leading to the source of electricity is electrically connected by a conductor that is inserted in a tight manner in a glass tube, I, capable of movement in a stuffing-box in the wall of the vessel to the upper part of each of the bells E, such upper part being made of electrically-conducting material, whilst the lower part of each bell, which dips in the mercury, is either made of, or covered with, a non-conducting material. The upper part of the bell thus constitutes the anode. The negative terminal wire is connected to the mercury. Instead of being slidden along rectilinearly, the bell E, or the vessel A, or the bottom of the latter, may have a rotary motion imparted to it. An arrangement of apparatus of this kind is shown in Figs. 7 and 8. Here the vessel A, which contains the mercury cathode C, is constructed in the form of a disc provided with an upwardly projecting edge and the hub of which is fixed on a vertical shaft K that is rotated by suitable means. The decomposing and combining chambers are formed by means of fixed radially arranged bells E which are connected together so as to form a cover provided with partitions, as in the arrangement shown in Fig. 1. The decomposing and combining chambers follow each other in succession and are respectively provided with the chlorine discharge pipe F, and with pipes H for discharging the hydrogen. A number of such disc-shaped vessels A, with radially arranged bells E, may be mounted one above the other upon one and the same shaft. Also the disc-shaped vessels A may be fixed, and the bells E be mounted on the shaft K so as to rotate therewith, which is equivalent to the more reversal of the apparatus described with reference to Figs. 7 and 8, and requires no further description. The manner of operation is the same as before described, in all cases. If it be desired that the alkaline metal shall be rapidly removed from the amalgam formed, then in the case of apparatus of the kind herein described, there may be employed the method specified in claim 7 of the specification of my British patent No. 17,169 of A.D. 1892, whereby the heat liberated in the formation of amalgam is converted into electrical energy. For this purpose, into the trough B of the apparatus (Fig. 9), or into the bells E (Fig. 6), or into the combining cells of the bells E (Fig. 7), that is to say, always in the chamber in which the separation of the sodium is to take place, there is suspended a third electrode G which is electrically connected in any suitable way to one of the terminal wires—viz., that extending from the mercury cathode (Figs. 6 and 9), thereby forming a short-circuited secondary element composed of the mercury cathode C and the electrode G, which element effects the rapid separation or removal of the alkaline metal from the amalgam. Each third electrode G may be carried either by the corresponding bell E, or by the bottom of the vessel A, through any suitable connection which should be of non-conducting material, or be covered with such material.

"Having now particularly described and ascertained the nature of the said invention, and in what manner the same is to be performed, I declare that what I claim is:

"1. An apparatus for the electrolysis of metallic salts with the aid of a stationary mercury cathode, in which partitions or bells capable of being moved to and fro, and dipping into the said mercury cathode, are arranged to separate the decomposing and combining spaces or chambers from each other, and by their to-and-fro movement to cause the mercury cathode to be located alternately within the sphere of action of the electrolyte and of the substance to be combined with the cation produced, substantially as hereinbefore described with reference to and illustrated by Figs. 1 and 2 of the drawings referred to.

2. The modification of the apparatus specified in the preceding claim, in which the movable petitions or bells are provided with pipes, H H^1, for carrying off hydrogen, and are arranged in a closed vessel, A, which contains the mercury cathode, and is provided with a pipe, F, for carrying off chlorine, substantially as hereinbefore described with reference to and illustrated by Fig. 6 of the accompanying drawings.

3. The modification of the apparatus specified in claim 1, in which one or more vessels, A, is or are mounted on a vertical shaft, so as to be capable of rotating relatively to the fixed partitions or bells that dip into the mercury cathode carried by the said vessel or vessels, or in which the said partitions or bells are capable of rotating in a fixed vessel or vessels, substantially as hereinbefore described with reference to and illustrated by Figs. 7 and 8 of the accompanying drawings.

4. In apparatus of the kind specified in the preceding claims, the arrangement of a third electrode G in the combining-chamber or in each such chamber, the said electrode G, or each of them when there are more than one, forming with the mercury cathode a short circuited secondary element, for the purpose of rapidly removing the alkaline metal from the amalgam substantially as hereinbefore described with reference to and illustrated by Fig. 9 of the accompanying drawings.

5. In apparatus of the kind specified in the preceding claims, the arrangement of slots or notches e or b^2 in the edges of the partition or bells, or in the bottom of the vessel that contains the mercury cathode, for the purpose of obviating displacement of the mercury when moving the partitions or bells relatively to the vessel, substantially as hereinbefore

Digitized by Google

described with reference to and illustrated, by Figs. 4 and 5 of the drawings herein referred to."

Mr. Fletcher Moulton, Q.C., M.P., Mr. Bousfield, Q.C., M.P., Lord Robert Cecil, Q.C., Mr. J. C. Graham, and Mr. A. J. Walter appeared for plaintiffs; Mr. T. Terrell, Q.C., Mr. Astbury, Q.C., Mr. W. Dixon McConkey, and Mr. J. H. Gray represented defendants.

Mr. MOULTON, in opening the appellants' case, said they had brought the action for the purpose of obtaining an injunction to restrain the respondents from infringing the above-described letters patent, granted to Carl Kellner, for an invention entitled "Improvements in electrolytic apparatus for decomposing metallic salts," and for the delivery up of all infringing apparatus. So far there had been no infringement by the respondents, and for that reason these proceedings were curious, for in order to get the question settled whether, if the respondents proceeded to do that which they stated they intended doing, it would or would not be an infringement of the plaintiffs' rights, the defendants had admitted that they intended to use an apparatus similar to that described in the Specification of Letters Patent 21,509, of the year 1896, granted to Rhodin.

The LORD CHANCELLOR: Then the action was brought to restrain the use of such apparatus by the defendants which the plaintiffs alleged, if used, would be an infringement of the two patents—the Castner-Kellner patents—which the plaintiffs are now the holders of?

Mr. MOULTON replied in the affirmative, and, continuing, said before the date of the invention, which was the subject of Kellner's patent, there were many methods of obtaining by chemical action caustic soda which were in more or less common use, and were never the subjects of any patent: but they all had this disadvantage, that the soda obtained was never really pure. Kellner's related to an apparatus for the manufacture of caustic soda by passing a current of electricity through a solution of common salt (chloride of sodium) in water which had the effect of liberating chlorine at the anode and sodium at the cathode. It was known that in such an apparatus if the cathode was a layer of mercury the sodium would enter into combination with the mercury, forming a fluid amalgam of mercury and sodium, and that this amalgam might be subsequently decomposed by the action of water into mercury and caustic soda. In all the apparatus which had been in use prior to the date of Kellner's patent, the arrangements depended upon causing the mercury to circulate by means of pumps and the like through pipes or suitable passages, so that the mercury took up sodium in one chamber and was then caused to pass into another chamber where the mercury was wholly or partially freed from sodium; the mercury being then returned to the other chamber to take up a fresh charge of sodium, and so on. In Kellner's invention the provisional specification described the charging of the mercury with sodium and its subsequent discharge as being effected in this way.

It was common ground that caustic soda was produced by a process which, shortly described, was this:—A solution of common salt in water was subjected to an electric current while in contact with mercury, the effect being that the sodium in solution was precipitated into the mercury and formed an amalgam, while the chlorine, which was also contained in solution, was driven off in the form of gas. This amalgam was then subjected to the operation of water, the chemical effect being that the sodium in the amalgam of mercury and soda combined with the oxygen of the water forming oxide of sodium. The water thus impregnated was then evaporated or otherwise dealt with, the product resulting being caustic soda. The chamber in which the amalgam was produced was known as the "decomposing chamber," that in which the sodium was extracted from the amalgam as the "combining chamber." Thus the mercury was charged with and discharged of the sodium, and the operation could be repeated with the same body of mercury for an indefinite number of times. Now, one of the apparatus devised for carrying out the process was one which Castner took out a patent for in 1892. It provided a means of producing caustic soda by a continuous process, carried on by means of a quantity of mercury moving round and round in its containing vessel.

The LORD CHANCELLOR: I gather that the essential characteristic of that invention was a moving body of mercury. The respondents contend—and it was so found by the Master of the Rolls and Lord Justice Rigby—that by the words "stationary mercury cathode," used in Kellner's provisional specification, the patentee meant a mercury cathode which was stationary with respect to surrounding objects, and that as the mercury as used in Kellner's complete specification was situated in a rotating vessel, this apparatus so described and claimed was such a departure from the invention disclosed in Kellner's provisional specification as to render the letters patent invalid.

Mr. MOULTON: That was a part of the argument that would be dealt with later. But he would point out that the apparatus which was claimed in the complete specification was not only a legitimate but a very obvious and natural modification of the apparatus described in the provisional specification, and that unless such a modification could legitimately be covered in the complete specification, the invention would practically be left unprotected.

The LORD CHANCELLOR: In this provisional specification the invention consists in moving "to-and-fro" the mercury; in the complete specification the mercury, or at any rate the vessel containing it, is kept stationary. I understand that the defendants said the patent is bad on the ground of disconformity, and that is the view that the court below took of it.

Mr. MOULTON: That is really the only ground that the Court of Appeal decided against us on. I shall contend that the complete specification is simply an amplification of the provisional specification.

Lord MORRIS: There are two peculiarities in this case: first, the plaintiffs' patent has never been used for any commercial purpose, and its non-user is not explained by the fact that although new and useful when obtained, it has been superseded by a later invention; and, secondly, that the defendants have not begun work, so that no infringement, in fact, can be proved by what they actually have done.

Mr. MOULTON explained that the defendants were about to put an apparatus on the market which the appellants believed was covered by their patent. When the two processes were being described in court, Mr. Terrell made this admission. He said, "If there is no distinction between a rotatory movement and the to-and-fro movement described in Fig. 1 of Kellner's specification, then there is no other practical distinction between my (Rhodin's) apparatus and theirs." Kellner showed in his provisional specification one mode of carrying out his invention, namely, by a "to-and-fro" motion of the vessel or bell containing the salt solution. But it was quite competent for him to point out in his complete specification any better method of presenting the mercury first to the salt water and then to the fresh, provided he kept the mercury as quiescent as possible.

Lord MORRIS: In his judgment, the Master of the Rolls said, "I am not prepared to hold . . . that the mere substitution of a rotary motion for a to-and-fro motion of the bells would not be equally within Kellner's invention, as described in his provisional specification, provided always care were taken to keep the mercury still. But there has been an entire departure from the essential feature of his invention as originally described. Here the mercury is intentionally not kept as still as possible, but may be moved and disturbed to any extent. This is quite inconsistent with the original idea. An invention for keeping the mercury still is not an invention for keeping the mercury moving. Claim 3 covers both inventions, and is such a departure from, and such an extension of, Kellner's real invention as to render the patent sued upon invalid as it stands."

The LORD CHANCELLOR: Does not the real question we have to decide come down to this:—Whether your patent—whether it is good in itself or not—is not too wide, and therefore bad? Your patent is for a mechanical arrangement by which the mercury previously stirred about was reduced to a state of stillness.

Mr. MOULTON submitted that the patent rested solely in the arrangement of the apparatus. Therefore, in the complete specification Kellner was justified in describing a modification of his apparatus which was shown in Figs. 7 and 8, and claimed in the first part of the third claiming clause. According to this form of Kellner's invention the mercury was still allowed to be at rest relative to its containing vessel, but the vessel containing the mercury was moved while the bell remained stationary instead of the converse arrangement previously described. It was a modification of the invention, against the use of which by others the inventor was entitled to be protected.

The LORD CHANCELLOR: I see on this point Mr. Justice Bigham said, "I think what Dr. Kellner meant to convey was that the mercury was to be stationary with respect to its containing vessel."

Mr. MOULTON: Yes, my lord. "Stationary with respect to its containing vessel" is the point on which the argument really turns, having regard to the fact that up to 1894 a flowing body of mercury stirred about had always been in use, and that before the date of "Castner" the mercury had been run off into another vessel. "Castner" took a vessel and divided it, keeping, however, the amalgam continuous in the two parts, and transferring it from one part to the other by means of a paddle.

The LORD CHANCELLOR: Yes, he kept it stirred up.

Mr. MOULTON: But Kellner obtained his result by moving one part of the cell relatively to the other. That was a striking novelty to move about in the middle of a fluid an electrolytic cell which contained another fluid. He gave to the public a means of obtaining a movement by means of moving rigid parts instead of moving a fluid, which in some cases, as where the apparatus is large, might be of the highest importance.

The LORD CHANCELLOR: I cannot help feeling that the result is obtained by contradictory methods—rest and motion—and you say the defendants have taken all that is shown in this provisional specification.

Mr. MOULTON contended that stationary cathode in the provisional specification meant that without moving the cathode the effective motion could be produced of one part of the cell relatively to the other, without the need of employing fluid motion. An inventor was free to amplify his invention between the times of filing his provisional and complete specifications, provided that the principle was the same in both. "Woodward v. Sansum," 4, R.P.C., 174. An amplification was here necessary because the inventor saw that someone might use his invention without infringing his patent; for, as the provisional specification stood, the movement of the bell might be in any direction and to any extent, and he might have any number of them. Again, it would have been an infringement of this provisional to have kept the top still and moved the bottom and, to avoid it, the patentee described and claimed it. It was no objection to a patent that there was invention between the provisional and complete specifications so long as it was the development of the same idea.

The LORD CHANCELLOR referred to the case of "Newall *v.* Elliot and Glass," 4 C.B.N.S., 269, in which it was laid down that the office of the provisional specification was only to describe generally and fairly the *nature* of the invention, and not to enter into all the minute details as to the manner in which the invention was to be carried out, which was the case when the complete specification was filed.

Mr. MOULTON said that was a case in his favour, although it was distinguishable from the present case. There, in the complete specification the rings claimed were not mentioned at all in the provisional specification. In the present case nothing was mentioned in the full specification that was not also mentioned in the provisional. The only difference was the addition of another way of working the apparatus in which the same result could be produced. The nature and the character of the invention were described the same in both specifications.

The LORD CHANCELLOR: In his judgment, Mr. Justice Byles said: "But the office of the provisional specification is only to describe generally and fairly the *nature* of the invention, and not to enter into all the minute details as to the manner in which the invention is to be carried out; otherwise the provisional specification must be as full as the complete specification, and drawn with as much care and deliberation. Indeed, the statute itself indicates this distinction between [the provisional and the

Digitized by Google

final specification, for it calls the latter the *complete* specification, implying that the former is or may legally be, in some respects, executory and incomplete. Moreover, it enacts that the provisional specification is to describe the *nature* of the invention, and no more; but when the statute comes to speak of the complete specification its language is altogether different. It enacts that the complete specification shall describe not only the nature of the invention, but also the manner in which it shall be performed, and not only describe, but particularly ascertain it." It was that last sentence that I have read this passage for to the court, for it seems to me all important.

Mr. MOULTON submitted that Kellner was not by his provisional specification limited to a particular form of moving bell, and it could not be an unfair development of a moving bell to move the bottom and keep the bell still. He contended that the method in which the plaintiffs' invention was to be performed as described in the complete specification had, in fact, been so described in the provisional specification.

The LORD CHANCELLOR: There, at present, I am not with you. I should like you to read now the judgments of the courts below.

Mr. MOULTON then read the judgments given by Mr. Justice Bigham and the Lords Justices in the Court of Appeal.

The LORD CHANCELLOR: As I before pointed out in the provisional you claimed one thing, and you made your complete specification so large that it included something that was not in the provisional specification at all. What have you to say on the second point—that of infringement?

Lord MORRIS: If Kellner's patent of 1894—the one sued on—can be shown to be invalid, the second question as to infringement does not arise.

Mr. MOULTON replied: In that case the discussion on infringement no doubt would be academical merely; but he desired to go through the evidence given at the trial before concluding his argument.

The LORD CHANCELLOR: In order to support what proposition?

Mr. MOULTON replied he desired to refer to the evidence with a view of showing that there was absolutely no difference in the effect produced by moving the mercury under the chamber and moving the chamber over the mercury. The learned counsel, having referred at some length to the evidence given by Lord Kelvin and other witnesses on this point, submitted that the invention described and claimed in the complete specification was not larger than or different from the invention described in the provisional specification, which was valid and properly the subject matter of a patent. In conclusion, he repeated the reasons given in the judgments delivered by Mr. Justice Bigham and Lord Justice Vaughan Williams as those upon which this appeal should be allowed.

Yesterday (Thursday) the arguments were continued, and

Mr. BOUSFIELD said their lordships would remember that there were three chief matters at issue. The respondents alleged that the specifications were imperfect, insufficient, ambiguous and misleading; that gave rise to the second question of disconformity; and third, there was a question of infringement. Mr. Justice Bigham and the Master of the Rolls and Lord Justice Vaughan Williams held, although deciding against the appellants, that Kellner's invention was a good, novel, and useful patent; Lord Justice Rigby on this point, although in favour of the respondents, also differed from the Master of the Rolls. Mr. Justice Bigham and Lord Justice Vaughan Williams held, on the second question, that the modification in the working of the apparatus as stated in the complete specification was within the provisional specification; while the Master of the Rolls and Lord Justice Rigby took a different view. Then, on the question of infringement—

The LORD CHANCELLOR: Is that question substantially in issue?

Mr. BOUSFIELD said it certainly was. At one stage this question for a time was shelved, but before this House it would be necessary to consider and decide it. He desired to take for his text, on which to argue, a passage from the judgment of the Master of the Rolls, as giving very clearly the definition of the appellants' patents. The Master of the Rolls said: "I pass now to consider the first point which arises in this case, and that is the nature of Kellner's invention as disclosed in his provisional specification. The invention is for an improved apparatus. The real nature of that invention is, in my opinion, quite clear. It is an apparatus for moving an open-mouthed vessel containing an electrified solution of salt over a stationary layer of mercury covered with fresh water. The vessel is to be moved in such a way that the electrified salt solution shall be in contact with part of the mercury for a time, and then be shifted to another part, whilst the mercury first acted upon by the salt water, and converted into an amalgam of mercury and sodium, shall be brought into contact with the fresh water, so as to decompose the amalgam into mercury and soda in solution. That was Kellner's invention, and, so far as I can judge, it was novel and useful."

The LORD CHANCELLOR: The real issue between the parties appears to me to be this. Do the words "stationary mercury cathode" in the specification mean a stationary cathode composed of mercury, *i.e.*, a stationary mercurial cathode or a cathode composed of stationary mercury? The Master of the Rolls took the view that the word "stationary" referred to the vessel in which the cathode was contained. So far you will, I take it, accept his definition; but you will contend that the Master of the Rolls was wrong when he went on to say that one of the essential features of Kellner's invention was the keeping of the mercury as quiet as possible consistently with moving the bells of salt water over its surface.

Mr. BOUSFIELD replied in the affirmative, and said the specification spoke of "flowing" mercurial cathode. He desired to explain the method employed by Castner by which the mercury was kept stirred up, whereas in Kellner's the process was one of quiescence. The Court of Appeal treated this question as purely academical, and viewed it from a jurist's and not a scientific standpoint. The cathode which, he contended, had not necessarily a relation to the vessel that contained it, was the medium through which the electric current passed, but that cathode, as far as mechanism could produce it, was kept perfectly still. The vessel that contained it might be whirled round, but the cathode, as far as possible, was kept in a state o quiescence. Kellner wanted to keep the mercury as still as possible during the operation. He brought the mercury into "contact" with the bells, which just dipped into the fluid. Thus it would be seen that the *modus operandi* of his apparatus depended on allowing the mercury to remain at rest within its containing vessel. By the motion of the bell the mercury was alternately brought into contact with a salt solution and with water surrounding the bell. Castner did not move any part of the bell, but he had a stirrer, shaped like a screw propeller, for the express purpose of stirring up the mercury in order to obtain a uniform richness of sodium. This result could also be obtained if the cell were kept stationary and the containing vessel moved from the bottom about the bell. Objection was taken that the plaintiffs did not use Kellner's apparatus, but there was nothing in that objection, for they used a rocking apparatus instead as being more convenient. He then referred to Lord Kelvin's evidence in support of his contention that there was no practical difference between a "to-and-fro" and a "rotatory" motion of the mercurial cathode. On the objection that the complete specification went so much farther than the provisional specification as to describe a different invention from the one described in that document, he cited a passage from the judgment of Lord Justice Lindley (as he then was), given in "Gadd and Mason *v.* Mayor, &c., of Manchester," 9 R.P.C., at p. 526, where he said, "Although it is quite true, as observed by Sir H. Davey and Mr. Carpmael, that the object of the patent [an improvement in gasometers] being old the patentee must be tied down to the modes of obtaining that object described and claimed by him, it is, in my opinion, wrong in point of law, even in cases of this kind, to tie him down to the particular methods shown in the provisional specification. But it is only by so tying him down that his patent can be held bad for want of conformity. Even under the present law the court may be driven to hold a patent invalid on the ground that the invention described and claimed in a complete specification is not the same as that provisionally protected. . . . If a case is on the border line, the patent ought to be held good rather than bad."

The learned counsel was about to argue the third issue when their lordships intimated they did not desire to hear the question of infringement at that stage in the proceedings.

Mr. TERRELL, Q.C., for the respondents, then addressed their lordships. After Mr. Terrell came Mr. ASTBURY, Q.C., on the same side, who had not concluded his argument when the Court adjourned until Monday.

Bulstrode and Others v. Julius Sax and Co. (Ltd.)

In the Queen's Bench Division, on Friday last, before the Lord Chief-Justice and a special jury, an action was heard, brought by Edward Bulstrode, Thomas Wilson, Emil Bahter, Wm. Krause, and John Plumb (carrying on business under the style of the Saxon Electrical Engineering Co.), to recover damages from Julius Sax and Co. (Ltd.) for libel. Defendants admitted publication, and the jury was asked to assess damages.

Mr. RAWLINSON, Q.C., for the plaintiffs, said the five plaintiffs were, previously to July of last year, in the employment of Julius Sax and Co. and afterwards of Julius Sax and Co. (Ltd). Mr. Bulstrode had been in the employ of the company for 20 years, and the other plaintiffs also held positions in the old firm. Towards July last year it became clear that the old company would not be able to continue their business for long, and at the beginning of August plaintiffs made up their minds that in case anything happened to the old firm they would set up on their own account as electrical engineers. The company were in difficulties, and sold their business to Mr. H. M. Salmony, who practically had formed a new company, which took over the business. At the beginning of August Mr. Salmony, who was in negotiation for the purchase of the business, approached plaintiffs with a view of their staying on in his employment, but these negotiations fell through, and on August 12 plaintiffs gave notice to leave. On August 19, their notice having expired, the company put up a notice saying they had gone into voluntary liquidation and all the employés of the company might consider themselves dismissed. The plaintiffs then sent a circular to various persons they knew in business stating that the firm of Julius Sax and Co. (Ltd.) having gone into voluntary liquidation, they (plaintiffs), who had been the heads of certain departments of the old company's business, had formed themselves into a syndicate to carry on the business of electrical engineers and electric light contractors, assisted by several other of the late employés of the old company. On September 4 defendants published a circular letter (which was the libel complained of) to the effect that it had come to their knowledge that certain discharged employés of the firm had sent out to the company's customers a circular containing misleading statements which might possibly be injurious; that the matter had been placed in the hands of their solicitors, who would take steps to put an effective stop to such statements; that the firm of Julius Sax and Co., which had been established for 50 years, was recently reconstructed with a view of introducing additional working capital and more rigorously prosecuting the business, which would be carried on as theretofore, while the services of such of the former staff who had proved themselves capable and competent had been retained. On behalf of plaintiffs, Mr. Rawlinson submitted that that circular suggested that plaintiffs were discharged, that they had made misstatements, and were incompetent, and that defendants did not think it right to retain their services. Plaintiffs had failed to obtain an apology.

For the defence, Mr. H. M. SALMONY said he negotiated for buying the business of the old firm, and ultimately did so by an agreement of July 27, 1899. He re-sold it on August 24, and it was still carried on as Julius Sax and Co. (Ltd.). He had had many consultations with Mr. Bulstrode about the purchasing of the business, and told him he was going to form a company to take over the business and carry it on just as it was before. He had an interview with Mr. Bulstrode about his staying on, but they could not come to terms. The question of offering an apology to plaintiffs

Digitized by Google

was left in his solicitors' hands. Evidence was also given by Mr. Arbuthnot, manging director of the defendant company.

Mr. RUFUS ISAACS, Q.C., said the plaintiff Bulstrode had no possible justification for using the list of defendants' customers in sending out his circulars. The retort of the defendants was, under the circumstances, perfectly reasonable, as he had imputed in the circular what was not the fact, namely, that the company was defunct. Again, the name of plaintiffs' company was extremely similar to that of defendant company, and he thought Mr. Bulstrode had some idea that by means of his circular he was going to get the benefit of Julius Sax and Co.'s business. This was a war of circulars, and while defendants had sent out a circular which could not be justified, he submitted that plaintiffs had done exactly the same thing.

Mr. RAWLINSON said there was no evidence of this imputation about the list of customers or similarity of name, and if the plaintiffs had done the defendants any wrong in these regards, the defendants could bring an action against them now, and it was also open to defendants to be counterclaimed in the present action.

In summing up, the LORD CHIEF-JUSTICE said in this case the libel is not denied, and it is not pleaded that there is justification. In considering the point of damages, the jury are entitled to take into account the circumstances of the case, and the conduct, not only of the defendants, but of the plaintiffs also, and to what extent the plaintiffs conduct may have suggested that which is here complained of as libel, especially in relation to what amount of damages the plaintiffs were entitled to get. In actions for libel—and often in cases of most serious libel, too—it is impossible for plaintiffs to prove pecuniary loss, but damages may be given although not a farthing of pecuniary loss is proved. In this case plaintiffs had been for a number of years in the employ of the original firm of Julius Sax and Co. During a portion of this time that firm, it was admitted, was not in a healthy financial condition, and Mr. H. M. Salmony came forward to buy the whole business, wind up the old company and form a new company. With this object the old company went into voluntary liquidation in July, 1899, and Mr. Salmony entered into a contract to buy, for £3,000, all the assets of the old company, which shortly afterwards disappeared from existence. Then the new company was registered. This being the state of affairs the five plaintiffs met together for a perfectly legitimate purpose—to co-operate to form a new firm and to carry on the same kind of business which they had assisted in carrying on whilst employés of the old firm of Julius Sax and Co. This they had a perfect right to do. They gave notice to determine their service with the old company, and it was, therefore, untrue that they were discharged by the old company, and this is a most important point to bear in mind in this action. The defendants did not justify that statement and it was not true that any of these five persons were discharged employés of the old company. The five plaintiffs thereupon issued a circular, and it would be for a jury to decide how far that circular went, not to justify, but to palliate the libel complained of. Defendants complained that this circular was calculated to do injury, not to the old company, which was not in existence, but to the new company, which had taken over the business and goodwill of the old, and he (the Lord Chief-Justice) held that however the wording of the circular might have been arranged, the same amount of injury might have been done to the new company. But the plaintiffs had a perfect right to form themselves into a syndicate to carry on a similar business, and the language used in their circular was literally true. Again, the defendant company were perfectly justified, within certain lines, in counteracting any injurious impression which such a circular might have created, so long as the lines of such circular were the lines of truth. But instead of this a circular was distributed which contained statements that were untrue. The new firm of Julius Sax and Co. (Ltd.) did not discharge the plaintiffs. The statements made by the plaintiffs in their circular were not misstatements but were true statements, and the announcement made by defendants that "the matter has been placed in the hands of our solicitors, who will take steps to put an effective stop to such statements" was calculated to injure the new firm legitimately formed by the plaintiffs. If the defendants' contention that an improper use had been made of the list of the old firm's customers, or by the use of the word "Saxon" in connection with the title of the plaintiff's new firm, then the defendants had, and have still, their remedy against the plaintiffs. When the jury had given such damages as they thought right to the plaintiffs, it was still open to defendants, if any legal wrong had been done to them, either by the use of this list or by the use of the word "Saxon" to take such action as they might be advised to take. The most vicious part of the libel was, however, that part of defendants' circular which notified that "the business will be carried on precisely as heretofore by a thoroughly competent staff, and under the guidance of well-known electricians, while, at the same time, the services of such of the former staff as have proved themselves capable and competent have been retained," and, further, "in order to prevent servants, whose services we have not thought it right, in the interests of the company, to retain, from prejudicing our customers, we think it is only necessary to call your attention to the above facts." Here it was undoubtedly intended to convey that the new company had got rid of the riff-raff employés of the old company, only retaining the competent and capable men; therefore the men (the plaintiffs) who are sending out the circular calling attention to the establishment of the new syndicate are incompetent and incapable. He (the Lord Chief-Justice) need not point out that such statements were not justified. Therefore the plaintiffs are entitled to such damages, as, taking into consideration the action of both parties, the jury might consider adequate.

The jury returned a verdict for plaintiffs for £250—£50 for each of the plaintiffs—for which judgment was entered.

It transpired that defendants had paid £10 into court as sufficient to meet the plaintiffs' claim.

Dobell v. Marshall and Another.

This case came before Mr. Justice Lawrance and a special jury in the Queen's Bench Division on Tuesday, and was an action to recover £90 for arrears of salary from June 9 to October 13, 1899, and also damages for wrongful dismissal.

It appeared that plaintiff, an electrical engineer, was interested in some patents for obtaining electric energy direct from coal. He assigned the patents direct to the defendants, in whose employment he was for some years, and a syndicate was formed, and plaintiff was paid £5 a week and employed his time in experimenting with a view to bringing the invention to perfection. The experiments, however, were interrupted between the dates mentioned, the plaintiff receiving no salary. In October more money was obtained and a fresh arrangement made by which plaintiff was to receive a salary of £7 a week and 5,000 shares in a syndicate or company to be formed. He proceeded with the experiments until the end of October when he was sent an agreement to sign which contained terms different from those which had been previously arranged. Plaintiff declined to sign and was shortly afterwards dismissed at a week's notice, and now claimed damages for wrongful dismissal. The syndicate was a failure, and was wound up on April 21, 1899.

Mr. TINDAL ATKINSON, Q.C., for defendants, said that during the period for which shares and salary were claimed the plaintiff was not conducting experiments at all. The money in the hands of the syndicate had given out. Defendants denied employing plaintiff for a fixed term.

The jury returned a verdict for defendants.

PARLIAMENTARY INTELLIGENCE.

MANCHESTER AND LIVERPOOL EXPRESS RAILWAY.

The Select Committee of the House of Commons, over which Sir John Kennaway presides, on May 5 began the consideration of the bill of the Manchester and Liverpool Express Railway Co., by which power is sought to incorporate a company for the construction of an electric railway on the mono rail system between Manchester and Liverpool. It is intended to run one-car trains at a speed of 110 or 120 miles an hour. Petitions against the bill were lodged by the Cheshire Lines Committee, the Lancashire and Yorkshire Railway Co., the London and North-Western Railway Co., the Corporation of Salford, and others.

Mr. BALFOUR BROWNE, Q.C., for the promoters, said the proposed railway would begin almost in the centre of Manchester, and terminate in the centre of Liverpool. There would be no intermediate stations, and it was only proposed to run express trains for passengers between the two towns, so that there would be no competition with the other railway companies as to the local or goods traffic. There was a growing feeling in favour of rapid transit, but it was agreed that the limit of speed in the present system of railways had been almost reached. Electric traction had, however, opened up a new field and offered great advantages compared with steam traction. On the ordinary railway the cars and the locomotive were only kept on the way by comparatively small flanges on the inner tire, and the centre of gravity was far above the wheel base. In 1891 two Continental engineers were able to obtain a speed of 150 miles an hour on a railway from Vienna to Budapest, constructed on the present system; but to allow that speed the line had to be perfectly rigid, and the cost of construction was practically prohibitive. Mr. Behr, the originator of the new system, had for many years considered that to obtain great speed a change would have to be made in the construction of the permanent way and carriages, and he was the first to bring into vogue the mono-rail system, which would be that adopted in the propored undertaking. A single rail was laid on the top of trestles about 4ft. high, on which the weight of the car was carried. Below the top rail were two guiding rails, which bore the lateral pressure when the car was rounding a curve. In 1886 a line was constructed on this principle from Listowel to Ballybunnian, in Ireland, on which steam locomotives were used. It had been proved that curves of 54ft. radius could be safely rounded at considerable speed. The trestles would be of steel and bolted into sleepers. The motors would be carried under the lower part of the car, and the centre of gravity would be 14in. below the top rail, making derailment absolutely impossible. The centrifugal force was met or taken up by pressure on the guide rails. Trials were made in Brussels in 1887 which demonstrated that the system was practically successful. A road 3 miles long was laid in the exhibition grounds, 75 per cent. of which consisted of curves, and, with only 500 H.P. of electricity, a speed of 83 miles an hour was attained without difficulty. The car on that occasion weighed 70 tons, but it was proposed on the new railway to construct cars of a weight, including motor, of 45 tons, which they considered would be quite sufficient. A special commission appointed by the Belgian Government had thoroughly tested the line at Brussels, and the chief engineer of the State railways would inform them that it would be quite possible to attain a speed of 120 miles an hour with perfect safety. This immunity from risk was one of the special advantages of the new system. Following a lecture delivered by Mr. Behr to the Chamber of Commerce of Liverpool in 1899, a committee of investigation was appointed and a company formed to promote the construction of a railway on the new system between Manchester and Liverpool. The electric power station would be at Warrington, and the electric current would be carried by conduits along the line. At the transformers the voltage would be reduced from probably 10,000 to 500 or 600. The electricity would then pass along the guide rails to be taken up by the guide rails and conveyed to the motor in the car. The length of the line, which would be double—an up and down line—was 34 miles 4 furlongs 5 chains, and the cost was estimated at £1,750,000, of which £401,600 was set down for land and buildings. This did not include the equip-

Digitized by Google

ment. The capital proposed to be authorised was £2,000,000 in ordinary shares and £660,000 in debentures. With the consent of the authorities of the House, the engineers proposed to show the Committee a model of the train at work. As to the danger of collision, there would be a separate up and down line without junctions, stopping places, or level crossings, and the only possible danger was of one car overtaking another on the road. By a system of automatic "lock and block" signalling this danger would be avoided, as the signal would be reproduced in view of the engineer travelling on the car. The working of the railway would be much cheaper than on an ordinary railway, the experience of the Overhead Railway at Liverpool and the City and South London Electric Railway proving that the cost of electric traction was 1s. 3d. or 1s. 4d. per train mile, as compared with 2s. 9d. to 3s. 3d. cost of steam traction on the Great Western and London and North Western railways. On the proposed railway they expected to run at the rate of 110 miles an hour, covering the distance between Manchester and Liverpool in 20min., and they would have a 10-minute service. As to the prospects of the company, at the present time there were on the various railways 4,500 passengers daily, and with increased speed and frequent services they considered the number would largely increase. They calculated that assuming their estimates of cost were correct they would be able to pay 5 per cent. on the share capital of the company. Counsel then dealt with the opposition to the bill, and concluded by calling

Mr. HAWKSHAW, C.E., vice-president of the Institution of Civil Engineers, and joint engineer with Mr. Behr in laying out the proposed line, who said the line began at Deansgate, Manchester, and terminated at the Bluecoat school in Liverpool. The construction of the line presented no engineering difficulties, and the estimate of the cost was ample. Taking into consideration the construction of the railway, he did not think there would be any danger of derailment in rounding sharp curves even at the speed of 110 miles an hour. The absence of points and crossings diminished many of the sources of danger on ordinary railways.

Mr. F. BEHR, the originator of the system, and the joint engineer of the proposed line, said he had for 14 years considered the development of the mono-rail system for electric traction, and he and his co-workers had spent £200,000 in experiments. Under the present system of double rails it would, in his opinion, be impossible to get a high speed owing to the presence of points, level crossings and signals. He had arrived at the conclusion that the maximum of speed had been attained on the existing railways—60 miles an hour; and that it was impossible to apply electricity to double rails with any hope of very high speed. From his experience of the trials at Brussels, upon which £60,000 had been expended, he thought that on a properly constructed line on his system, it would be possible to attain a speed of 110 or 120 miles an hour. In this experiment they reached 83 miles per hour, but the line was only three miles in length. The experiment had excited so much interest that the Belgian Government had appointed a commission to inquire into the subject. He had brought the question under the notice of commercial men at Liverpool and Manchester, and the result was the formation of a committee, who reported that the system had stood as severe a test as any new invention could be put to short of practical application on a commercial scale, and that it was possible, without extra risk, to reduce the period of travelling between Manchester and Liverpool to 20 minutes. They further reported that if the terminal stations could be arranged near the exchanges there would be a large increase of traffic. He had selected Liverpool and Manchester because they are just at the right distance to prove the commercial value of his scheme. As this district was chosen for the experiment of the two-rail system, he thought it desirable it should be selected for the experiment of the mono-rail system. They proposed an improved communication. The express service between the two towns was as well done as it could be, but it was done at the expense of the local service. At present the goods traffic was neglected, and the docks were greatly congested. All the cars would be double-flanged. As to the danger of collision, electrical brakes could be made to act even at a high speed; and he had invented an air brake which would reduce the speed of a train going at the highest speed. The danger of derailment would be very much reduced by the absence of points and level crossings. The dangers of an ordinary train were derailment (which on his system was impossible) and collision (which on his system was very improbable). The signals under his system were reproduced before the eyes of the conductor, and it was very unlikely that any collision could occur. So by his system he decreased many of the dangers and increased the general safety. Witness described the route of the proposed line, which, commencing at Deansgate, Manchester, proceeded almost parallel with the lines of the Cheshire Lines Committee to Liverpool. He had made a deviation at Liverpool to meet the wishes of the Lancashire and Yorkshire Railway Co. and the Mersey Docks and Harbour Board. His proposal was to start a carriage with 64 passengers, propel it to Liverpool at a high speed, and follow it every 10 minutes by a second carriage over the same route, the only danger of a collision being a breakdown in the signalling or in the power to stop. In that way the service would be twice as quick and three times as frequent as at present.

Mr. S. POPE, Q.C., for the opponents of the measure: Do you suppose that everybody wants to be shot through the air at 100 miles an hour?—I have travelled at the rate of 90 miles on my own line at Brussels, and I did not feel any different sensation to that I experience when I travel in any ordinary express train.

When you were dealing with the possibility of some wicked boy or of some member of the public putting an obstruction on your line, you said that the existence of a line heavily charged with electricity would be such a colossal danger, that no one will be likely to go near enough to put a stone on the line. What would be the damage if he did?—It is obvious that unless he knows where the current is and is technically informed of the danger, he would run great risks from two sources—the electric current and a train travelling at 110 miles an hour rushing suddenly upon him.

What voltage do you propose to use?—The Board of Trade will settle that ultimately, but if I could get all I want, which I very much doubt, it would be 1,000 volts.

Let us consider what you are really asking. Take Salford. Do you expect that the municipality of Salford can see that colossal danger carried through their borough without remonstrance?—In the case of Salford, this colossal danger is carried on a viaduct without steps, the lowest part of which is 24ft. high and the highest 60ft., so that in order to be affected by it a person would have to be a really clever acrobat.

You admit, I presume, that the presence of this electric current and of a train rushing through the air at 110 miles an hour would constitute a real danger unless care was taken by the public?—Yes, but in exactly the same way that every existing electric railway must be a source of danger.

Concluding his evidence, Mr. BEHR said he had estimated the passenger traffic quite irrespective of the number of people carried at present. He estimated that 7,500 passengers would be carried daily. That was not a large estimate for a population of nearly 2,000,000. In his opinion, in the end, when the people get accustomed to travelling, they would not be able to carry all the people with the service they now proposed, and many would have to go by the present train service. As a proof of this he could give the figures of the Liverpool Overhead Railway. In the old times about 2,000,000 of people travelled by the omnibus service; in 1895, the first year of the railway, 5,000,000 of passengers were carried, and last year the number had risen to 10,000,000. Taking the present traffic, he estimated the revenue would be sufficient to pay interest at 5 per cent. on the ordinary share capital. Electric traction, carried out on the system of light and frequent trains, was much cheaper than steam traction. He had put down 50 per cent. of the receipts for the expenses, but he believed the cost would be nothing like that amount. In his opinion, this railway would cause such a relief of the through traffic that the other railway companies would not suffer, and they would be able to give extra facilities to their goods and local traffic. He thought everything had been done to test the invention which could be done without Parliamentary authority.

The LORD MAYOR OF MANCHESTER (Mr. Thomas Briggs) said he was of opinion that greater dispatch was necessary in the traffic between the two towns, especially in the cotton trade. The time taken by the express train was 45min., and if this could be reduced to 20min., and the number of trains increased, there would be certainly a large increase in the passenger traffic.

Mr. R. E. COOPER, C.E., said he had had large experience in railway works and had examined the plans of the proposed railway and the details of the construction of both the permanent way and the cars. He considered the proposal feasible. The line would convey passengers with perfect safety at a high rate of speed. The electric traction offered many advantages over the steam railway. The ordinary locomotive had to carry its own fuel, which the electric car had not. On an American railway, between Buffalo and New York, the Empire State Express had attained a speed of 70 miles an hour, but this was quite exceptional. He knew the Budapest railway, which was nearly straight, an advantage that could not be obtained in England. The benefit of the mono-rail system over the double-rail was that on going round a sharp curve at high speed the outer rail on the double-rail system would have to be raised to overcome centrifugal force. Neither of these disadvantages applied to the mono-rail system. By the present system a speed of over 60 miles an hour was commercially impossible. The new line seemed to him to offer a more than ample reserve of safety. He had examined the estimates which had been submitted by the promoters, which he considered were sufficient.

M. ERNEST GERARD, engineer-in-chief of the State Railways of Belgium, gave evidence of the results on the experimental line near Brussels. This line was three miles long in the shape of an ellipse, and 75 per cent. of the line consisted of curves. In his opinion the proposed line avoided the danger of derailment and would give greater safety than the ordinary permanent way. The weight of the carriage at Brussels was nearly 72 tons, but with a carriage properly constructed the weight could be largely reduced and the speed very much increased. In his opinion, a speed of 100 to 110 miles an hour could be easily and safely attained. The present Belgian Government did not consider it expedient to incur the expense of railways on Mr. Behr's plan to extend the present railway system. It was, however, quite possible that another Government might have a different opinion. At Brussels the highest speed attained was 94 kilometres an hour. After travelling through the circle once it was not possible to attain the maximum speed on account of want of power and the somewhat sharp curves. At certain points he had himself observed a speed of 120 kilometres.

Mr. F. C. Dawson (F. C. Dawson and Co., Liverpool), Mr. J. H. Macmillan (managing director of Messrs. Sales, Schwabe and Co., Manchester), Col. Robert Bridgford (J. R. Bridgford and Son), and Sir W. H. Bailey (W. H. Bailey and Co., Salford) spoke of the strong desire in the district that the scheme should be carried out.

Sir W. H. PREECE said he had carefully studied the plans of the proposed railway which was to be worked by electricity on the mono-rail system. It was proposed to have a generating station at Warrington, almost at the centre of the line, and a most convenient place for coal and water. The current would be generated on the high-tension multi-phase principle at Warrington and there transmitted by transformers located along the line. The correct term for the system proposed is rather tri-phase, because it consists in transmitting from Warrington to each end of the line three alternating currents following each other in succession. The advantage is that these three currents following each other prevent any external disturbance. That system of distribution was eminently suitable for the purpose. They had ample experience of working it in America, in Switzerland, and in Dublin. The cable would carry 1,000 H.P. and would be laid about two or three feet below the surface. In the case of viaducts it would be in iron troughs built into the viaduct. After the current got to the transformers it would be trans-

Digitized by Google

formed into a current of very much less pressure. At intervals of three or four miles along the line there would be sub-stations. These sub-stations would be brick-lined pits in the ground. In these sub-stations would be placed transformers which would either be fixed transformers, transforming the voltage from 10,000 to 1,000 or may be rotary transformers, transferring the tri-phase currents into continuous currents. The transforming would be done by induction, and the currents so transformed and reduced in pressure would be picked up by the train to actuate the motors. If the line was properly constructed, and the conditions of the Board of Trade complied with, there could be no danger to human life. There would be no interference with the electrical signals of any other railway. They were now working a section of the Metropolitan Railway where there were delicate electrical signals at work, and there was absolutely no disturbance from the currents of that line. In this scheme the weight of the electric train proposed to be run would be about 45 tons, and the speed 110 miles an hour. To attain that speed as soon as possible there would be a down gradient from the stations at each end. The departure from a station would be downhill, and the approach to the station would be uphill. That aided very much in the acceleration of the train, and enabled the high speed to be kept up till nearly the end. Electric traction had two merits over steam or locomotive practice. The first great merit is that you can at once apply through your motors the absolute maximum power required to produce a certain acceleration. They could at once apply, if needed, either at Liverpool or Manchester, at the starting of the train 2,000 H.P. The second was that the electric motor is a constant application of force. The wheel bites the rail with a constant grip so long as your current is on. With a locomotive the grip is reciprocating, or rather it is variable. The grip is not constant, that is why the driving wheels slip. Witness gave an interesting illustration of this fact. On the Metropolitan District Railway, he stated, on the line between Earl's Court and High-street, Kensington, there happens to be a very awkward incline of 1 in 43. We selected that length for the preliminary test because it contained that awkward gradient. Our train weighed 180 tons. We weighted it up with pig iron to 220 tons, representing a train carrying 800 passengers. The locomotive people were rather anxious to try their locomotive against an electric motor. The locomotive weighing 50 tons was attached to the train, which thus weighed 270 tons. We went on this incline and stopped. We shut off our current and then asked the locomotive authorities to put on their steam. They did. The wheels slipped, but the train did not move. They could not move the train. So our turn came. The current was put on, the train walked up nicely with the 220 tons plus the locomotive of 50 tons. Then, to show the power we had on this incline, we set the two against each other. The locomotive was put in opposition. So the electric motor had not only to take its 220 tons, but it had to work against all the power the steam could bring against it. We walked up. Electricity was victorious.

Continuing, WITNESS said one of the great advantages of electric traction was that you could generate the power at a central station and with the greatest possible economy. If the proposed train was run throughout the day at a 10 minutes' interval there would be a very constant load; and with constant loads and large stations they could produce the power at the cheapest possible rate. He was quite sure it was perfectly possible to attain the high speed desired. There was certainly no electrical risk, and he could not see any mechanical risk. The question of brakes was one to which he had given considerable attention. It was very difficult to give an opinion because they had no experience of brakes on trains going at the rate of 110 miles an hour. The experience of air brakes did not extend beyond a speed of 70 miles an hour. How the brake would act at 110 miles an hour was a question of experience and not of opinion. He certainly thought it possible, as Mr. Behr proposed, to throw out louvres or shutters in front of the train to increase the air resistance. In his opinion they would be able to stop a train going at 110 miles an hour in 1,500 yards. An electric brake was possible. It was theoretically easy to apply the current on a brake, but that of course was a thing which was quite the subject of experiment. As to the signalling there would be no need for any signals except at Manchester, Warrington and Liverpool, which would be on the lock-and-block system of automatic signalling. On the line everything would be done by electricity: the signals would be raised, the switches worked, and everything done by the current. Then they could automatically, if necessary, have a section of the line without any current at all, so that if a train passed its signals it could not move. By that means he thought security would be made more secure. There would also be along the line—from end to end—a telephone circuit which would give the driver of the train the power at any time to communicate with Warrington, or Manchester or Liverpool. And it was possible, and even easy, to give the driver, by wireless telegraphy, the means of communicating to his two terminal stations from any point of the line when he was in motion.

Mr. BALFOUR BROWNE: Apart from wireless telegraphy it is possible to telegraph from trains in motion at the present time by induction?—That is what I mean by wireless telegraphy. People seem to imagine that whenever they hear the word "wireless" telegraphy that it is the Marconi system. Wireless telegraphy existed as a practical thing long before Hertzian waves were heard of, and long before Mr. Marconi came to this country. We at the Post Office have for the last 18 years (since 1882) been working very carefully and very assiduously on that very subject.

WITNESS proceeded to deal with the estimate of working expenses. Taking the trains as running every 10 minutes in the morning and night, and every quarter-of-an-hour during the middle of the day, the car mileage would be 1,500,000 miles a year. He estimated the cost of locomotive power would be 5·57d. per car mile, and the total cost of working 11·97d. per car mile. These estimates were based on a car mileage of 1,500,000 miles a year, and on the assumption that the energy required from the the generating station per car mile would be 7·5 kilowatts. Witness gave a long and detailed statement of the connection between horse-horse and currents and the construction of motors. At 110 miles an hour the driving wheel would have to go at the rate of 750 revolutions per minute. These revolutions were well within the margin of safety. There are many machines at work, working up to 10,000ft. per minute, and Parsons' and Laval's steam turbines work at 30,000 revs. per minute.

In cross-examination by Mr. Worsley-Taylor, Q.C., WITNESS said the greatest speed got by electric traction had been 85 miles an hour, on the experimental line at Brussels. He believed they had got to 60 or 70 miles in America, but the highest speed he had known in his experience was 39 miles an hour on the Metropolitan line.

Mr. S. B. COTTRELL, who attended in pursuance of an order of the Speaker, said he was engineer and general manager of the Liverpool Overhead Railway. That railway was about 6½ miles long and was carried al ng the whole dock front of Liverpool and Bootle. He had been a member of the sub-committee appointed to enquire into the feasibility of the present proposal, and in his opinion by the mono rail system the risk of derailment was overcome, and a much higher rate of speed could be secured than was possible on the two-rail system. He thought the anticipated speed of 110 miles a little high, though they could possibly at short intervals and with short sections attain 100 miles. As to the question of brakes, electrical brakes were used in America, and on the General Electric Co.'s system, in New York, they stop the train at the rate of 5½ft. per second. His experience of electric traction proved that with a frequent service the cost was very much below steam traction. On his railway what might be called the locomotive cost was 4½d. per train mile, whilst on the great railways the cost varied from 8d. to 11d.

Mr. H. F. PARSHALL said he was resposible for the designing of the electric plant on the Central London Railway. He had read the proposals of the bill, and was satisfied that a speed of 110 miles an hour could be attained without any excessive expenditure of energy. There were a good many lines in America at the present time where they got a speed of 60 miles an hour, and they were becoming more popular and the rate of speed was being increased. They could get a speed of 45 miles or 50 miles an hour on the Central London Railway if they desired, but they had only half-mile runs. That line was 6 miles long, and the whole journey would take 25 minutes. To make that speed the trains had to get up to a speed of 30 miles an hour between stations to make an average running time of 15. He saw no reason why 110 miles or even 150 miles should not be attained. The only limit to speed was the cost of obtaining it.

Dr. EDWARD HOPKINSON said he had no doubt whatever that the trains could run on the line as proposed with safety and economy at a very high speed. He considered 110 miles an hour a practically safe speed. The system of construction called the mono-rail was a highly advantageous system for the purpose. He should place the limit of speed to be obtained on any electrical system at from 120 miles to 130 miles an hour. This limit was governed by the strength of the materials used. The cost of the electrical equipment of this line would be between £450,000 and £500,000.

This was the whole engineering evidence and numerous witnesses were examined to prove the desirability of the railway from a business point of view, and as to the estimates for land and property to be acquired (£451,600).

Mr. W. MATHER, M.P., said he was of opinion that the Brussels tests had been conducted on an unusually large scale for experiments, and that the next step that should be taken was the construction of a railway under such conditions as was here proposed in this case. He thought this scheme provided an opportunity that should be seized by the railway companies in order to discover by what means in the future they could accelerate their express traffic, and run the traffic at a cheaper rate, at the same time relieving the congestion upon their lines. He had thought they would desire to know how far electrical power could be used to move express trains, and had hoped that, instead of opposition, they would have given every encouragement to the enterprising men proposing to make this railway. He looked upon this railway, in fact, as a pioneer scheme, and an important object lesson to the whole country, and with the hope, indeed the anticipation, that for the sake of its benefits the companies would be willing to run the risk of some reduction in their passenger traffic. He (Mr. Mather) would be glad to invest money in the scheme, and would advise his friends to do so.

This concluded the case for the promoters.

Mr. R. SMITH, for the District Council of Irlam, contended that it was unfair that for some theoretic advantage to Manchester or Liverpool the interests of his large district should be seriously and permanently injured. This bill, which did not pay any attention to the interests of the district through which it passed, should not be favoured by the Committee. Parliament should require that a railway traversing a district like theirs should provide for the local as well as the terminal traffic.

The MAYOR of SALFORD (Ald. S. Rudman), Ald. PHILLIPS, and Mr. J. CORBETT (borough engineer) stated that the new railway would disfigure the borough and depreciate property.

Mr. BEHR was recalled and examined by the Chairman as to the possibility of carrying the railway in a tunnel through Salford. He said the tunnel, unless of enormous sectional area, would not allow of the speed being attained, and would cost three times the money. Moreover, the public would not like to travel in a tunnel at 110 miles an hour. With a tunnel the journey would probably take 25 min. instead of 20 min.

Yesterday (Thursday) Mr. FREEMAN, Q.C., addressed the Committee on behalf of the Salford Corporation, and Mr. LITTLER, Q.C., for the Cheshire Lines Committee. The latter urged that the measure was an ill-considered one. Mr. SQUAREY spoke for the Garston District Council, and called two witnesses to prove there was no public demand or necessity for the proposed railway, Sir WILLIAM POLLITT, general manager of the Great Central Railway Co., gave evidence, and the proceedings were adjourned.

METROPOLITAN DISTRICT RAILWAY BILL.

The Select Committee of the House of Commons, presided over by Col. Cotton Jodrell, on Thursday last commenced the consideration of this bill, which, among other objects, authorises the erection of electricity works at Lots-road, Chelsea, for the generation of power for the operation of the Metropolitan and Metropolitan District Railways by electricity, and the laying of mains for the distribution of current at points near Warwick-road and West Brompton stations. Opposition to the bill came from the London County Council (who object to the one main running through the public streets) and the West London, Great Western, and London and North Western Railway Cos. (who object to the other main running over ground belonging to them *en route* to Warwick-road).

Mr. S. POPE, Q.C., for the promoters, said the Metropolitan District and Metropolitan companies had a general power of working by electricity, but the real difficulty in electric traction was in dealing with lines where ordinary locomotives had also to be used. It had not been found that the question of the movement of heavy goods by electricity had yet been solved. The question of the use of electricity on the railways had been engaging the attention of the two companies, and since 1897, with the assistance of Sir J. Wolfe Barry, they had been engaged in experiments to solve the problem. They thought they had now arrived at a solution, and it was hoped that, if the present bill passed, electric traction would within a short time supersede steam. It was sought to acquire a site on the banks of the Thames, at Lot's-road, Chelsea, for the erection of a generating station, from which the electric power would be conveyed for use on the railways by means of two lines of pipes conveying cables, which would prevent any question of electrolysis of gas pipes. One of the cables would run by way of the public streets to a point on the railway at Warwick-road, and the other would pass by the west side of Chelsea, past Brompton Cemetery, to near West Brompton Station. The two lines were necessary to provide an alternative power in the event of failure or obstruction. To the second line there was opposition from the West London Railway, over some of whose unoccupied land it was proposed to pass.

Sir JOHN WOLFE BARRY, K.C.B., described the experiments that had taken place between Earl's Court and High-street, Kensington, which he said had proved so great a success that trains would within a week be run for passenger traffic between those points. The cost of substituting electricity for steam traction over the portions now scheduled would be £500,000. Electric traction would be used between Putney and the Mansion House, or perhaps Whitechapel, but not at present on the Hammersmith route. Its use would be confined to the underground lines. The site for the generating station was a most convenient one, providing plenty of condensing water, and coal could be brought to the works at the least expense. It was under consideration to take another site at the North of London for the supply of the Metropolitan Railway.

Sir WILLIAM PREECE, K.C.B., said he had given evidence before Lord Cross's Committee of 1898, which had recommended the use of electricity on these lines. The experiments, he considered, had shown that electricity would revolutionise underground railway travelling in London, solve the question of ventilation, make the trains more comfortable, cleaner, lighter and quicker, and many people who now used cabs and omnibuses would then travel by them. The proposed site for the generating station on Chelsea Creek was considered with great care. Before Lord Cross's Committee he had pointed out the serious consequences of the multiplication of generating stations in London. Last year there were applications to Parliament in respect of 43, and this year there were many more. There was the smoke nuisance, as Welsh coal could not always be obtained. Then, in addition, there was the congestion of traffic caused by the delivery of coals and the removal of ashes, which traffic through the streets was an objectionable one. Taking London altogether, with its 70 or 80 generating stations, the matter was a serious one. These objections were removed by placing a generating station on the river, as was now proposed, as the coals and ashes could be dealt with by water. The nuisance was also prevented of the clouds of steam passing into the air, and dropping in the form of rain into the adjoining streets, as plenty of water was available for condensing purposes. Each of the proposed mains would carry 1,000 H.P. Ordinarily there was a magnetic influence from a cable, so much so that the currents on the South London Railway affected the instruments at the Greenwich Observatory so that certain investigations had to be abandoned. But by the conductors proposed to be used there would be no external field, no disturbance of any sort or kind. There would be no electrolysis, and the West London Railway might feel absolutely assured that the laying down of these mains alongside their line would have no disturbing influence either upon telegraphs or telephones. This was due to the fact that the currents to be used would be alternating—in turn each conductor would become a return for the other. This was known as the tri-phase system, and each conductor in turn being subject to alternation of current prevented all outside influence. There would be a dynamo at the station generating three currents following each other, which would work at 10,000 volts, and the current would be transmitted to Earl's Court. There would be ten sub-stations along the route of the lines where the 10,000 volts would be reduced to 500 volts, at which pressure the trains would be worked. Another source of disturbance was leakage to earth from bad joints or defective insulation, but any leakage in this case would simply be from one wire to another affecting nothing outside. The cables would be laid either in another pipe or, as he preferred, in iron troughs filled with pitch. He did not believe inspection would be necessary once in five years.

This closed the case for the promoters, and after hearing witnesses for the London and North-Western Railway Co., the Great Western Railway Co., and the London County Council against some of the clauses of the bill.

On Monday the Committee decided to pass the preamble of the bill The clauses were afterwards considered, and the bill ordered to be reported to the House.

CITY OF LONDON ELECTRIC LIGHTING CO.'S BILL.

This bill came on Wednesday before the Select Committee of the House of Commons, presided over by Mr. A. H. Brown. The opponents of the bill were the Corporation of London and the Vestry of St. Saviour's, Southwark, but the latter opposition was, early in the proceedings, settled.

Mr. BALFOUR BROWNE, Q.C., in opening for the bill, said the company were authorised under several provisional orders to supply electricity within the City of London. When the company was first authorised to supply electricity the Commissioners of Sewers were the authority with which the company had to deal, and all their orders were founded on contracts obtained with the Corporation of the City of London. Under those agreements the company were laid under most onerous burdens, but they got what they thought was a *quid pro quo*, that was, the exclusive right to supply electricity in the City. By the agreements the City of London Co. were obliged to set aside various reserve funds. First of all, out of the revenue of the Company they had to take 7½ per cent. on the value of the capital for a depreciation fund, to be used for the maintenance, renewing, or replacing the machinery and appliances necessary to the undertaking. In addition, 5 per cent. had to be laid away for reserve fund—not applicable to dividend—before any profits could be divided. Under these provisions very large sums had been laid away. The 7½ per cent. depreciation reserve No. 1 now amounted to £71,826. 2s. 2d., and the depreciation reserve No. 2 to £37,107. 18s. 10d., and the reserve fund to £16,349. 6s. 6d., a total of £125,283. 7s. 6d. The whole of this was invested in gilt-edged securities. If it could be used in the company's undertaking it would be there used at the ordinary rate of percentage, but as it had to be invested, they were practically getting nothing upon this enormous sum of money. It was the bargain that these monies were to be set aside, but for doing so, the Company were to have an exclusive right of supply in the City, and until last year they had enjoyed that right. At that time the Charing Cross and Strand Electricity Supply Corporation were allowed to obtain powers to come into the City, the Corporation being advised that the agreements entered into with his company were void. A week or two ago Mr. Justice Farwell had decided that those contracts were not void, but the mischief had been done. The Charing Cross Co. had got into the City, and competed with the City of London Co. free from the obligations that had been imposed on that company. What was now asked was that as the Charing Cross Co. had been let in the City of London Co. should be put on the same basis as that company, and freed from those obligations. It would be in the interest of the consumer that this should be done. If the £125,000 could be put to capital account it would bear no dividend, and therefore the company would be able to manufacture electricity more cheaply, and sell to the public more cheaply. The only other provisions of the bill were for the extension of the company's generating station in Southwark, and for erecting certain workmen's dwellings.

Mr. J. CECIL BULL, manager and secretary to the City of London Electric Lighting Co., gave evidence in support of counsel's statements. The subscribed capital of the company on Dec. 31 last was £400,000 6 per cent. preference shares and £800,000 ordinary shares. In addition to that there were £400,000 5 per cent. debentures, making £1,600,000 in all. The company had 1,900 customers, and supplied 460,000 8 c.p. lamps. The gross revenue of the company was, in 1899, £187,253, and the net revenue £87,323.

Cross-examined for the City Corporation, WITNESS said he did not say that nothing would be put aside as a depreciation fund if the proposals of the bill were passed. The majority of the electric lighting companies invested what they placed aside in their business, and that was what the City Co. desired to do.

The promoters' case being closed, counsel for the Corporation addressed the Committee against the restrictions on the company as to the reserve funds being abrogated.

The Committee ultimately decided to pass the preamble of the bill, but limited the application of the reserve funds to capital purposes, not allowing them to be applied to dividend.

A clause was brought forward by the City Corporation for the restriction of the company's charges for electricity to such as were authorised in the case of the Charing Cross Co., but this the Committee rejected, but decided to insert a provision giving the Corporation certain powers of purchase over mains and so forth outside their jurisdiction but necessary to the supply of electric light within the City.

GOVERNMENT TELEGRAPH MESSAGES.

In the House of Commons yesterday (Thursday), Sir Edward Sassoon asked the Secretary to the Treasury if he would state the total amount paid during 1898-99 to the Eastern, Eastern Extension, Indo-European, and other associated cable companies for messages sent and received on Government service by the Foreign, Colonial, Indian, War, Admiralty and other Government offices.

Mr. HANBURY: There is no official knowledge except in the case of the India office of the amount of charges on telegrams sent from abroad over these lines to Government departments in this country during 1898-99. The charges on telegrams handed by the Post Office to these companies amounted to £21,976. This includes charges which the companies would have to pay out to various administrations for terminal and transit charges, but it does not include telegrams handed in direct to the companies and not through the Post Office. The War Office paid £3,016. 19s. 1d. direct to the companies in 1898-99, and the India Office £5,777. 11s. 1d., while the payments to India for Government messages home (including transit) are estimated at about £29,000. The Colonial Office and Admiralty never pay anything direct to the company. I have no figures available as to direct payments from other Government departments, but, excepting the Foreign Office, they are, presumably, of relatively little importance.

COUNTY OF DURHAM AND TYNESIDE ELECTRIC POWER BILLS.

The Special Committee of the House of Commons on Electric Power Bills recommenced, on Friday last, its inquiry into the partially-competing schemes of the County of Durham Electric Power Supply Co. and the Tyneside Electric Power Supply Co., Sir J. Kitson again presiding.

Mr. C. McLAREN, M.P., chairman of Palmer's Shipbuilding Co., Jarrow, supported the Tyneside scheme and favoured the idea of competition between the Durham Co. and the Tyneside Co.

Mr. EUSTACE SMITH, chairman and managing director of Smith's Dock Co. (Ltd.), South Shields, supported the Tyneside Co.'s Bill, and said he reckoned that if that company were allowed to serve the south side of the Tyne as well as the north side his company would save about £1,800 a year, on the schedule of prices proposed by the promoters.

Mr. SIMPSON, chairman of the Ryton District Council, and a large colliery proprietor, stated that water accumulated in one of his pits, and he had considered various methods of getting rid of it. Steam-power was not practicable, compressed air-engines were rather expensive, and electricity was found to be the cheapest power to employ. If he could obtain a supply of electric energy from the Tyneside Co. it would be of great advantage and would save enormous expenditure.

Lord KELVIN said he had satisfied himself that electrical power at a very high voltage could be safely transmitted for great distances. A current with a pressure of no less than 10,000 volts was being constantly transmitted between Deptford and Trafalgar Square, London, without danger. He regarded the scheme of the Tyneside Co. as a well-devised one and believed that it would provide electrical power in the cheapest and most efficient form. The compactness of the area on the two banks of the Tyne was an advantage, and it would be disadvantageous to plant the system on the edge of an area. The adoption of separate systems on the north and south sides of the Tyne would destroy in a great measure the desirable compactness of the area and would injure both the supply companies and the consumers because it would increase the expense. To limit the Tyneside Co. to the north bank of the river would be objectionable, especially having regard to the needs of the chemical industry. He was of opinion that, while competition in regard to detailed distribution was sometimes bad, competition for supplies in bulk was not bad. As to the allegation that it would be unfair to start a large electric power supply company in a district in which there were already bodies having powers of supply, he was of opinion that it was quite fair to allow anything to be done which would result in any benefit to the public. He thought it desirable that Parliament should, as far as possible, endeavour to facilitate the use of electric energy. The smallest quantity of plant by means of which electricity could be produced at an economical rate was that which would be represented by 1,000 H.P. In a scheme like this he thought that a start should be made with 3,000 H.P. or 4,000 H.P.

Mr. JAMES SWINBURNE said that, generally, he agreed with the evidence of Lord Kelvin. It was certainly desirable to establish large generating stations from which a cheap supply of electric energy could be given. A company could begin to supply really economically at from 4,000 H.P. to 5,000 H.P., and the greater the horse-power the more economical the supply would be, though the saving would not be very large, except in the case of a very large supply. He did not think there would be any harm in allowing the two companies to compete on the south side of the Tyne.

On Monday Mr. SWINBURNE again went into the box, and said there seemed to be some little confusion with regard to the size of the plant which could be worked economically; he wished to say that from 1,000 H.P. to 5,000 H.P. was the minimum at which electric plant could be worked with economy.

Replying to Mr. Ashton, Mr. SWINBURNE said the sliding scale proposed by the Tyneside Co. was in such a form that he did not think there would be any difficulty in working it.

Prof. S. P. THOMPSON agreed with Mr. Swinburne that from 1,000 H.P. to 5,000 H.P. was the minimum, so far as coal consumption was concerned, at which electrical plant could be worked with economy. He knew of no generating station which had grown so large that it had been found economical to reduce its size. He was of opinion that, in the interests of the district, the area of the Tyneside Co. should not be restricted to the north side of the Tyne. It would be obviously advantageous to the more economical working of such a station that the district to be supplied should be divided longitudinally. He had inspected some large power stations abroad, including Niagara and Rheinfelden, and in such cases it had been found very advantageous that the districts should be large and that the centres should be large. It had been of very great importance to the manufacturing industries that had grown up in and around Niagara, Rheinfelden, Paderno, and elsewhere, that the works should be on a large scale. In all these cases, no doubt, the power used was water power, but he apprehended that the economy would be the same in cases where steam was substituted for water power.

In answer to Mr. Bartley, WITNESS said it was the case that no generating station at present existed where 10,000units, mainly for power purposes, were produced by steam power. He thought it would be more advantageous to divide the Tyneside district by a line drawn from north to south, and to adopt the division of the river.

This closed the cases for the promoters of the two bills.

For the Tynemouth Corporation, Mr. J. F. SMILLIE, borough surveyor, stated that in 1891 the Corporation obtained a provisional order for supplying electricity for public and private purposes, but there was then no demand for current. In 1898 a firm of engineers advised them in regard to the setting up of an installation for the town. The works had now been begun, and unless the Tyneside Electric Power Co. were allowed to encroach on their area there was every reason to believe they would have to meet a very good demand for electric lighting. It would be possible to increase the supply if the demand increased. The Corporation would be in a position to supply current in a couple of months. He was of opinion that there ought to be a local monopoly, so far as the distribution of power in their own area was concerned. The Tyneside Co.'s schemes meant unfair competition, and to that the Corporation strenuously objected. The Corporation were willing to extend their works to any extent that might be necessary. They had already expended £35,000 on them.

Mr. SQUAREY, Q.C., having addressed the Committee on behalf of the Corporation of Tynemouth,

The CHAIRMAN said the Committee wished him to inform those of the petitioners against the bill who were local authorities, that the position of a manufacturer who was within the district of a local authority, and who wanted a supply in bulk was occupying their attention. If the local authority was unable or unwilling to give such a supply or to give it only at a prohibitive price the manufacturer under present circumstances must go without.

Mr. PAGE, Q.C., addressed the Committee for the Gateshead Corporation, supporting the Durham Co.'s bill and opposing that of the Tyneside Co. He called

Mr. N. TEMPERLEY, vice-chairman of the Parliamentary Committee of the Gateshead Town Council, who said that the Corporation had a right to buy, after the expiration of a certain period, the entire undertaking and goodwill of the companies which supplied Gateshead with electric energy for tramways and lighting. They thought it would be unfair that the Tyneside Co. should have a right of competing with the Durham Co. in the supply of electric energy in Gateshead, and they objected to the Tyneside Co. being allowed to put mains in their streets.

Mr. SHORTT then addressed the Committee on behalf of the petitions of the Gosforth and Wallsend District Councils against the Tynemouth Co.'s bill.

On Tuesday the CHAIRMAN said: I desire to state the procedure of the Committee. We propose to hear the promoters and the opponents of each bill before we give our decision. We shall give no decision on the Tyneside and the Durham bills until we have heard the cases for and against the other bills in our list. We have practically the direction of Parliament that there shall be uniformity in the clauses. As the cases are different, we might find principles in some bills which were not to be found in the others. The Committee therefore resolved to hear the whole series of bills before giving their decision.

Evidence was then heard in support of the petitions of the Hebburn and Felling District Councils against both the Durham and Tyneside bills, and Mr. PEMBER, Q.C., addressed the Committee for the Corporation of Newcastle. He stated that there were two electric lighting companies supplying Newcastle, and the Corporation had power to supply their own tramways with electric energy and to light their own streets. Though as a general proposition they could not oppose the laying of mains through their streets, they thought there were special circumstances in this case which rendered it unnecessary that they should be put to this undeniable inconvenience. If the promoters of the Tyneside bill had chosen the western side of Newcastle as a site for their generating station instead of selecting Wallsend, which was on the eastern side, it would have been unnecessary to lay mains in the streets of the city.

Mr. MORETON SMITH, for the Walker District Council, contended that, inasmuch as Parliament had given that body the right to supply electric energy and light, no other authority ought to be allowed to go into the district and compete with it. If the Committee tampered with existing companies and local authorities by passing a bill of this kind it would create a competitive supply of a most dangerous character.

Ald. J. M. REYNOLDSON, for the South Shields Corporation, said that in 1891 that Corporation applied for and obtained an order, under the Electric Lighting Acts, for the supply of electricity. The tramways belonged to them, and at the end of the present lease—which had five years to run—they proposed to substitute electric for horse-power. The Corporation's generating station was established and the supply was commenced in September, 1996. They began with only four or five consumers, but the demand steadily increased, and before the end of the first winter it was found necessary to increase the plant at the station and to extend the mains. In 3½ years their capital expediture had increased from £30,000 to £100,000. The Corporation were prepared to put in the proper plant for supplying at the cheapest possible rate all the large works within their area. They had been most anxious from the first to supply electricity for power purposes. The effect of allowing the Tyneside Co. to compete with them would be to jeopardise their electric power undertaking, in which the ratepayers' money was invested.

[Pressure on our space compels us to leave over Wednesday and Thursday's proceedings to our next issue.—ED. *E.*]

UNDERGROUND TELEGRAPH WIRES.

In the House of Commons on Friday, on the vote to complete the sum of £3,770,330 for the Post Office Telegraph Service, Mr. CALDWELL drew attention to the importance of underground telegraph wires. Owing to storms, the North of England and Scotland were frequently without telegraphic communication, and he suggested the laying of underground wires in order to meet cases of emergency, not entirely for the purposes of the telegraphic service. This system had been adopted on the Continent and worked well.

Mr. HANBURY said the underground wires laid between Birmingham and London were the only underground wires at present in this country, and were laid because that route was the principal course which the storms followed. It was an experiment, and if successful would probably be extended in other directions. The method of insulating wires was now better than it used to be and more economical.

Sir W. C. GULL drew attention to coast communication around Devonshire, and said there were several places where telephonic communication

Digitized by Google

was defective. He hoped proper arrangements would be made for the telephone service to be fully utilised when the coastguard was mobilised, and for the purpose of surprise practice with the lifeboat, especially at night. He asked that the lifeboat committee should be allowed to use the telephone.

Mr. HANBURY said that much had been done recently to extend telegraphic facilities. With regard to the use of the telephone at coastguard stations in connectious with lifeboat surprise practice, fears had been expressed that the alarm might be given too frequently, but he would see what could be done in this relation.

MUNICIPAL TRADING.

The Joint Commmittee appointed to consider the question of Municipal Trading held a meeting at the Lords Committee Room yesterday (Thursday), when the Earl of Crewe was elected chairman, and it was arranged to hold a further meeting to consider the course of procedure and to fix the date of the first meeting of the Committee.

PARIS EXHIBITION NOTES.

(FROM OUR CORRESPONDENT.)

PARIS, *Friday, May 11.*

As a set-off to the general unreadiness of the main exhibits, mentioned in my previous notes, a word of praise must be given to the German sections. Up to May 7 the only machinery at work in the electricity section were those installed by German firms, and in other sections of the exhibition the German exhibits showed a decided forwardness compared with those of other nations. This forwardness was taken advantage of when the lighting up of the exhibition was attempted on Sunday evening, May 6, after the thunderstorm. The success of this attempt, which could only have been partial in any case, was rendered almost futile, so far as the splendid electricity building was concerned, by a dastardly act on the part of a discontented workman (whether French or German did not transpire), who placed a quantity of sand in place of lubricant in one of the main lubricators of the fine 150-H.P. engine installed by the Vereinigte Maschinenfabrik Augsburg.

Another legitimate cause of complaint is the absence of official catalogues. The list issued by the British Commission is of some help to the visitor, although not by any means all that could be desired. It is all very well to set out that a certain exhibit is in "the gallery," but when the aforesaid gallery extends over a large area this direction is not sufficient, and my own patient endeavours to locate the Accumulator exhibits in "the gallery" were, after an hour's careful search, fruitless. Certainly, if the sectional catalogues to the Paris Exhibition are to be of service to foreign visitors they should receive considerable revision and be furnished with more adequate direction-marks. The expenditure of a little extra time and labour on the part of the compilers of these publications will merit and doubtless receive the benedictions of visitors. These remarks fully extend to the altogether inadequate sketch maps which accompany the British section catalogue, which, devoid of lettering, are of little service. A final word as to the catalogues. I learn there are to be 22 volumes in all, and that the price is to be 3fr. 50c. each, a trifle of, say, £3 sterling!

The outside shows form a conspicuous and attractive feature of the exhibition, and by far the most conspicuous, and at the same time the most popular, are those of an electrical or mechanical character. The "Plateforme Mobile," with its no-speed, half-speed, and full-speed tracks, is well patronised, and at 50 centimes per head must be a great success financially. It maintains its monotonous course with almost unfailing regularity, only occasional stoppages occurring—one on Sunday, May 6, lasted for about 15 minutes. Needless to say, during these occasional stoppages the motionless crowd looks very foolish, and has its work cut out to appear unconcerned. Such contretemps afford occasion for merriment to those who are not at the moment patronising the "Plateforme Mobile."

The electric railway, which circuits the fringe of the exhibition grounds, is immensely popular, and well it may be so, for here for 25c. a good view of the exhibition exterior and of the environs of the extensive area covered by the exhibition can be obtained with ease and comfort. There are five stations on the electric railway. The trains, which are very compact, consist of three covered carriages, with accommodation for about 200 passengers. The distance covered by the line is 4 kilometres of single track throughout, except for the short section required for the "yard." A 2-minute service is given, the entire journey occupying about 25 minutes. But few interruptions to the regular running have so far occurred, and singularly, one of these stoppages happened on May 6, at the time of the interruption to the moving platform, and passengers by both were able to regard one another for a brief space of about five minutes in unexpressed but no less heartfelt sympathy. The situation was not devoid of humour. The fare of 25c. covers the entire journey by the railway, and there is nothing to prevent ve passenger retaining his seat from early morn to dewy eve, except, fc some, the necessity for food and drink. This remark applies alss to the "Plateforme Mobile," which is open from about 9 a.m. to 7 or p.m., and traverses a course, for most of the distance, on the outsic of the electric railway. A few seats are provided on the full spee platform, and the number might with advantage be increased. We shall doubtless see more of the "Plateforme Mobile," which, like tl terrible switchback, has come to stay, and it is advisable, therefor to make it as comfortable as possible. Both the electric railway and the moving platform afford an easy means of getting from one point to another of the exhibition grounds.

So far there is no sign of the automobile within the exhibition, although means are at hand for easy wheeled progression. Outside the grounds, in every part of the city, the motor-driven vehicle is much in evidence. Hundreds (many hundreds) of two, three, four and five-wheeled vehicles, holding from two to eight passengers, are dashing through the noble thoroughfares of this the gayest of gay cities. And the public, ladies especially, patronise these smart turn-outs, which have caught on in Paris to an extent which is as general as it is surprising—and, moreover, as gratifying as it is extensive. Seen in considerable numbers, all the novelty (or perhaps peculiarity would be better) disappears, and so accustomed is the pedestrian in Paris to the presence of the motor vehicle that he or she steps back to allow it to pass without apparently giving it a second thought. Public opinion is in favour of the automobile in Paris, and the advent of the exhibition is the psychological moment for this class of vehicle to cement its unmistakeable popularity. A number of these vehicles are electrically driven, and it is this pattern that will prove the survivor, although there is a comparative absence of smell from the petrel motors in use on the Paris autos that has led to the condemnation of those of this type seen in the streets of London and our chief provincial and seaside towns. The legal charge for the hire of either horse-drawn or electric two-seat vehicles is 1fr. 50c. for the ride anywhere within the Paris area, but a good rule where stoppages are contemplated or a call has to be made, is to hire the vehicle by the hour at 2fr. The hire of larger vehicles of each class are, of course, charged on a higher scale. In each case a pourboire of 25c. is demanded by the driver.

The electric tramway service in Paris is an excellent one. In fact, the means of getting about the city by means of tramways and omnibuses is very complete, except that the advisability for obtaining a numbered ticket before attempting to enter the cars is little understood by the average Britisher. It may be explained that, without this numbered ticket (obtainable at all the stopping places of the cars and omnibuses), the chance of securing a seat outside is nil, and a seat inside is only possible after the numbered tickets are exhausted—*i.e.*, if you have been waiting an hour without a ticket the last comer with a ticket takes precedence. As the Paris tramways and omnibuses are very crowded this point is worth attention by those who affect this excellent mode of "seeing Paris."

It remains to be mentioned that tickets for the exhibition can be had at any price from 55c. to 1fr., the ruling price being 65c., and this notwithstanding that these ticket are clearly marked "Une Franc." Strangers to Paris should obtain their entrance tickets from the shopkeepers who advertise them in their windows, rather than from the street hawkers, although, doubtless, all are genuine. It should be pointed out that admission is by ticket only, and that tickets cannot be obtained of the officials at the entrances. There are two officials stationed at each entry; one takes the ticket and perforates it, the second relieving you of your ticket altogether. The first issue of these tickets of admission is said to have been 65,000,000.

I have said nothing concerning the hotels—not because there is nothing to say, but because every person I have spoken to on the subject has a different (usually melancholy) story to tell. One word of warning, however—endeavour to obtain accommodation at the best, for the best is, as ever, the cheapest. Above all, avoid the tourist ticket.

Ibero-American Charity.—The tenth anniversary festival of the Ibero-American Benevolent Society was held at the Whitehall Rooms, London, on Monday evening, under the presidency of Sir Weetman D. Pearson, Bart., M.P. A large gathering of the chief Spanish and Spanish-American residents in this country were present, and a gratifying account of the assistance given to deserving candidates for the charity was rendered by His Excellency Don Arturo Baldasano, president of the society. Thanks to the indefatigable efforts of the stewards and the numerous other friends, the society is enabled to continue the good work inaugurated ten years ago. To these funds a large number of telegraph men have for many years contributed, thanks largely to the untiring work of Mr. Ch. Gerhardi, the respected manager of the Direct Spanish Telegraph Co., who on this occasion responded to the toast of "The Stewards." The toast of the evening, "Success to the Ibero-American Society," was given by Mr. E. M. Underdown, Q.C., chairman of the Direct United States Cable Co.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Alleged Theft.—At Clerkenwell (London) Police Court last week, a clerk named Frederick Purton, lately in the employ of the Jandus Arc Lamp and Electric Co, was charged with stealing letters, the property of his employers. Mr. Adrian Jones, manager of the company's works at Hartham-road, Holloway, N., gave evidence that for some time past he had been convinced that letters of a private nature and private particulars in connection with the works were being purloined, and, in particular, that the two letters, the subject of this charge, had been stolen. The matter having been placed in the hands of a detective, Mr. Jones' suspicions were verified. The *modus operandi* adopted by Purton was to obtain copies of the typewritten originals of letters, and upon being charged with this offence, he asserted that "the letters referred to a branch of the electrical business in which he took a great interest"! A large number of letters were found at his residence in Ruthven-road, Westcombe Park, W. After hearing the evidence the magistrate (Mr. Chapman) asked the grounds upon which the charge of larceny was to be established. Solicitor for the plaintiffs replied that the paper on which the letters were written belonged to the company, but that, of course, was a trifle compared with the stolen confidential correspondence, the betrayal of which to other firms in the same way of business might seriously affect the company. Mr. Chapman, however, held that the charge of stealing could not stand. The offence committed was a very grave one, but, so far as the evidence went, it did not amount to larceny, and prisoner must, therefore, be discharged.

Asylum Lighting.—The new asylum to be built for the Middlesex County Council at Napsbury, at an estimated cost of £360,000, is to be provided with electric lighting plant. The specification is being prepared by the Council's consulting engineer, Mr. W. H. Massey.

Ayr.—The committee recently appointed "to consider and report as to the merits of gas traction as compared with electric traction" submitted a report to the Council last week, recommending the construction of electric tramways on the overhead trolley system at an estimated cost of £57,000. This report has now been adopted by the Council, and the committee have been instructed to appoint an engineer for carrying out the scheme, and to have the necessary specifications prepared and tenders obtained. The line will be constructed to the standard gauge.

Bath.—The City Council have come to an arrangement with a private syndicate for the construction of electric tramways in Bath and the neighbourhood. The syndicate include Sir James Sivewright and Mr. Leopold Hirsch, and they have agreed to reimburse the authority the expenses of their recent application for electric tramway powers. They undertake to lay down a complete system of electric tramways without any liability on the part of the authority, who will exercise their statutory powers to purchase the undertaking of the existing horse tramways, the promoters paying the purchase price to the Corporation. For the first four years the syndicate agree to pay as wayleave to the Corporation £400 a year, for the second four years £450, and subsequently £500 a year. The Corporation reserve the right to repurchase the undertaking at stated periods, and the syndicate agree to repair the track or to pay the authority an agreed sum for carrying out the work. A separate generating station will be erected, and current will not be taken from the Corporation mains.

Bury (Lancs.).—The Tramways committee recommend the adoption of the overhead trolley system on the local tramways which will be reconstructed to the standard gauge.

Cardiff.—The question of erecting a separate generating station for the proposed municipal electric tramways has been discussed and agreed to. It has been further decided to engage an electric tramway engineer, at a salary of £500 per annum. The appointment is advertised in another column.

Cheltenham.—Application has been made to the Local Government Board for sanction to borrow £3,185 for extensions of the electric lighting plant.

Chester.—The Lighting committee have been authorised to substitute incandescent electric lamps for 21 gas lamps in Newtown at a cost of over £400.

Chesterfield.—An inquiry was held on Wednesday into the application of the Corporation to borrow £25,000 for establishing electricity works. Councillor Robinson said a provisional order was obtained in 1894. The General Power Distribution Co.'s bill had brought electric lighting matters to the front, and as they had also received a memorial from tradesmen on the question of supplying electric current, they had decided to establish a municipal scheme which was estimated to prove financially successful in the first year. There was no opposition.

Dock Lighting.—The Leith Dock Commission have authorised their works committee to engage a consulting engineer in connection with their proposed electricity scheme.

Dublin.—The Lord Mayor (Sir Thomas Pile, Bart.) announced at the Corporation meeting on Wednesday that the Local Government Board had sanctioned the loan of £250,000 for electric lighting. There was no truth in the statement circulated that this loan had been refused: as a matter of fact the Board expressed an opinion that the scheme was one of great merit, and was well within the compass of the Corporation to carry out.

Edinburgh.—The Electric Lighting committee recommend the Corporation to increase the charge for electric current for private lighting from 3½d. to 3¾d. per unit, and to reduce the charge on public lamps from £14 to £13 per annum.

Evesham.—The Council are making inquiries into the advisability of establishing electricity supply.

Fire.—Early yesterday morning a fire broke out in the subway belonging to the Central London Railway at the Bank, London, caused by the explosion of a paraffin lamp. Considerable damage was done to the subway works, but no loss of life occurred.

Hanley.—As the accounts of the electricity department for the past year show a deficiency of £1,200 a special committee has been appointed to investigate the cause of so large a deficiency.

Hastings.—An inquiry was held last week into the application of the Council to borrow, among other sums, £1,584 for electric lighting extensions. There was no opposition.

Hindley.—A sub-committee is to report upon the advisability of establishing electricity works.

Hyde.—The Council have approved the joint scheme for connecting Hyde, Stalybridge, Dukinfield and Mossley by a system of electric tramways. It is proposed that the capital for the joint scheme should be contributed by each of the four corporations in equal shares, the profits or losses to be received or borne in equal proportions; that the tramway and equipment be laid and provided by a joint committee, who would also maintain the lines on the county main roads; that each corporation should maintain the track on all the roads within their respective districts; and that the installation and distribution of electric energy both for lighting and power should be under the control of the joint committee. The Hyde Council have further decided to join with the Dukinfield Corporation in applying to the Light Railway Commissioners for an order to construct and work such portions of the tramways in the proposed joint scheme as would be situate within the two boroughs, and the borough surveyor has been instructed to prepare the necessary plans and estimates. The capital is to be contributed by the two corporations in equal shares; the profits and losses are to be received and borne by the two corporations equally, and the undertaking will be worked by a joint committee, one-half to be appointed by each corporation.

The application of the Oldham, Ashton and Hyde Tramways (Ltd.) to the Board of Trade for a transfer of the tramways from the British Electric Traction Co. is to be opposed by the council.

Heckmondwike.—At the meeting of the District Council on Monday, the Electric Lighting committee recommended the acceptance of certain tenders for electric lighting plant. The tenders (which amounted to an aggregate of £14,842, an increase on the original estimate of the consulting engineer, Mr. W. C. C. Hawtayne, of about £1 500) were adopted. Mr. Hawtayne's original estimate was submitted over 12 months ago.

Infirmary Lighting.—The Marylebone (London) Guardians have decided to light their infirmary electrically. Independent generating plant, estimated to cost £5,500 (annual maintenance £903), is to be erected.

Inverness.—Last week the Electric Lighting committee recommended the Council to accept the tender of the Brush Co. for the supply and etection of electricity generating plant. An amendment was moved that the tenders be let out in sections, as it was contended there would be a saving of between £3,000 and £4,000 by this method. Ultimately an amendment for further inquiry was adopted.

Kingston-on-Thames.—The sixth report of the electricity department, covering the 15 months ended March, was presented to the Council on Tuesday evening. The total capital expenditure amounted to £50,674 out of £58,426 sanctioned. The works cost came to 2·608d. per unit, against 3·036d. in 1898; management expenses (£910) and interest and sinking fund instalment (£2,785) amounted to £3,695, so that the total cost per unit was 4·967d., compared with 5·984d. in 1899. The receipts for the 15 months amounted to £7,511 and the expenditure to £7,559, leaving a deficit of £47. 18s. 11d. against £1,112 in the previous year. At the date of the report there were 311 customers, representing an equivalent of 16,130 8 c.p. lamps connected, compared with 211 and 11,856 in 1898. 364,000 units of current were supplied to private consumers, and 99,845 for street lighting. A 200 kw. steam alternator is being put down to meet next winter's load, and will permit of 10,000 8 c.p. lamps additional being connected. Experiments are being made in lighting the side streets by incandescent electric lamps. The report was adopted, and application is made for £15,000 for extensions.

Digitized by Google

Kircaldy.—The Council has decided to proceed with their electric lighting and traction scheme, and the Tramways and Lighting committee has been empowered to engage a consulting engineer and to make arrangements for carrying out the project.

Leeds.—The Lighting committee decided on Tuesday to recommend the Council to apply for sanction to a further loan of £28,000 for electric lighting plant.

Light Railways.—The Colne and Trawden, Nelson, and Barrowford light railway orders have been submitted to the Board of Trade for confirmation. Objections to the two former must be lodged by June 6 and to the latter by June 1. The Spen Valley (Ravensthorp to Cleckheaton) and the Barnsley and District Light Railway orders have also been submitted to the Board for confirmation. Objections by June 9.

The Swansea Corporation decided on Wednesday to apply for powers to construct light electric railways in the district.

London Chamber of Commerce.—The annual meeting of this Chamber was held yesterday. The report, which was adopted, stated that 15 meetings of the electrical trades section had been held during the year, and a special committee had been appointed to consider and report upon the threatened municipalisation of electrical undertakings, and arising out of that a municipal trading committee was formed. The Council of the Chamber had addressed a communication to the Board of Trade objecting to the proposals in a number of provisional orders to insert clauses authorising municipalities to manufacture and deal in electrical fittings, &c., in competition with private firms. These provisions have since been withdrawn from the bills. Generally the action of the Chamber in this direction had been successful.

London County Council.—At Tuesday's meeting the Highways committee recommended that powers should be sought by the Council in one of the bills to be promoted in Parliament next Session to double the existing tramways in Battersea Park-road, Bermondsey New-road, York-road, Albert Embankment, and Wandsworth-road. The total length of the proposed tramways was 1 mile 1 furlong 118 yards, and the estimated cost of reconstructing them for an underground system of electric traction was £43,200. Also for power to construct a double line of tramways along the new street from Bermondsey New-road to Tooley-street. The length of this line was 3 furlongs 154 yards, and the estimated cost of construction on the underground system £14,000. It was also recommended that the Council should not appeal to the Board of Trade against the decision of the Light Railway Commissioners with regard to the Council's orders for (*a*) the Deptford, Shooter's-hill, and Woolwich light railway; (*b*) the New-cross, Lewisham, and Eltham light railway; and (*c*) the Clapham, Wandsworth, and Kingston-road light railway. A further recommendation was that the Council should appeal to the High Court against the decision of the magistrate at Southwark Police Court in the proceedings taken by the Council against the London Electric Supply Corporation in respect of its default in not having maintained a constant supply of electrical energy in the district included in the Corporation's Electric Lighting (Metropolitan) Order, 1890. The consideration of these recommendations was postponed.

The estimates were submitted for the year 1900-1. Amongst the items the Fire Brigade Committee estimated that the expenses of the electric light installation at the head office would be £435, and other electric work, £750; telephones and fire alarms, £9,000. The estimate of expenses of the Council acting otherwise than as local authority under the Electric Lighting Acts and Orders, and of receipts for fees for inspecting and testing meters, &c., were:—Expenditure—Salaries and wages, £850; gas and electric current, £95; stores and instruments, £350, and incidentals, £100; total, £1,395. The receipts for inspecting and testing electricity meters and of testing electric pressure were estimated to be £400. The expenses under the London Overhead Wires Act were estimated to be £100, and of expenses in connection with the preparation of schemes under the Light Railways Act, £500. The estimate for professional fees, &c., in connection with inquiries as to mechanical traction, was £500.

Luton.—An enquiry was recently held into the application to borrow £26,000 for electric lighting purposes. The town clerk appeared in support of the application, and the consulting engineer (Mr. Albion T. Snell) gave technical details of the scheme. There was no opposition.

Manchester.—The revised estimates of the Electricity committee, submitted to the Corporation on Wednesday, provide for £4,000 being handed over for the relief of rates. An amendment was moved by Mr. Lambert that the original estimate be adhered to. He said it was proposed to pay the £4,000 out of reserve. The reserve fund had been drawn upon to the extent of £21,000 during the year, leaving £12,000, and it was now proposed to take a further £4,000, leaving a ridiculously inadequate sum for such a department. Ultimately the revised estimates were approved, after an acrimonious discussion.

Melton Mowbray.—Tenders for street lighting from the Melton Mowbray Electric Lighting Co. and the local gas company have been referred to the Lighting committee for analysis and report. The electric lighting company offer to do the lighting for five years at £370 per annum, and to give illumination equal to 7,500 c.p. The gas company's tender amounted to £340. 11s. for 6,000 c.p. Last year's gas bill was £383, and the company only gave 2,140 c.p. There is consequently a disposition to favour the electric lighting tender.

Nottingham.—In consequence of the increase in the price of coal, the electricity department have decided to increase the price of current from June 30th. For lighting, 5d. per unit for the equivalent of 100 hours per quarter, and 2d. per unit beyond; for power, 1½d. per unit.

Overhead Telephone Wires.—At Bow-street (London) Police Court on Friday, the National Telephone Co. were summoned by the Strand District Board of Works, under the Overhead Wires Act, 1891, for failing to report the fixing of fresh overhead wires to the local authority. Inspector Gregory, of the Strand Board of Works, deposed that 180 wires had been erected by defendants between 34 and 35, Gerrard-street and 79, Wardour-street, W, since June, 1898, and, with one exception, no report had been made to the local authority of the fixing of those wires. Mr. Allsopp, for the defendants, contended that as the wires were not new there was no need to report. The wires had simply been diverted by the removal of a third standard which used to exist between these two. Sir Franklin Lushington held that a report was required, and imposed a fine of £5, and £2. 2s. costs. A second summons was dismissed on the ground that the wire was a renewal of one which had already existed.

At Bow-street Police Court, on Tuesday, Mr. Robert Williams, manager of Messrs. C. J. Grist and Co., electrical engineers, was summoned before Mr. de Rutzen, under the Overhead Wires Act, 1891, for failing to comply with the London County Council bye-laws as to the distance allowed between supports to such wires. Mr. F. Robinson, for the Strand Board of Works, said defendant's firm had fixed a private telephone wire between York-street and Tavistock-street with a span of 165 yards, the limit under the bye-laws being 115 yards. Inspector Gregory, of the Board of Works, said the span had since been reduced by 20 yards, and an attempt had been made to reduce it to 90 yards; but the insulator was not properly fixed, and rendered the wire more dangerous than before. A fine of 40s. and costs was imposed. On a second summons for failing to report the fixing of the wire, defendant was ordered to pay the costs. On a third summons charging him with failing to affix a distinctive mark to the supports, that the local authority might be able to distinguish them from those of other companies, a fine of 40s. and costs was imposed, the magistrate pointing out that firms such as defendant's must acquaint themselves with the bye-laws and comply with their provisions. [Contractors are advised that these and other bye-laws of municipal bodies are set out in "The Electrician" Electrical Trades' Directory and Handbook.—Ed. *E.*]

Partick.—Glasgow Corporation have agreed to supply current to Partick for lighting until the town's installation now being organised is completed. The supply is not to commence till Oct. 1, and the amount of current demanded is not to exceed 250 amperes at 500 volts for private lighting only. The price to be charged per unit is 3½d., and the period of supply 12 months. The Partick mains are to be laid by the Burgh Commissioners and the Glasgow Corporation is not to be responsible for any unavoidable failure in supply.

Plymouth.—The accounts of the Tramways committee for the past year were submitted to the Corporation on Wednesday. Mr. Page explained that there was an increase of expenditure of £1,689, of which £425 was due to the supply of electric current to the Prince Rock route. On the other hand, the receipts increased by £2,411, or 18 per cent. Of the total increase £1,855 came from the Prince Rock electric line and £850 from the Hyde Park and Compton section. He estimated the increased receipts arising from the use of electric traction at £435, and the extra expenditure involved in substituting electric for horse traction at £424, leaving only £21 as the net gain from the use of electric power on the Prince Rock line. There would be a greater advantage in the use of electricity on the Compton section. He estimated that the adoption of electric power for the Compton section to involve an expenditure of about £5,400 a year. Against that they would save by doing away with the horses and stables, £3,800, leaving £1,600 as the net extra cost of electricity.

Ripley.—The Ripley Co-operative Society are establishing electricity works.

St. Pancras (London).—On the recommendation of the Electricity committee the Vestry decided on Wednesday to lower the charge for electric current to places of worship and certain public hospitals in the district from 5d. to 4d. per unit.

Southampton.—The Corporation have received sanction to borrow £50,655 (out of £55,000 recently applied) to carry out electric lighting extensions. In the communication conveying consent the Local Government Board state that they have excluded from the

Digitized by Google

amount of the loan the sum entered for contingencies with the exception of 10 per cent. upon the estimated cost of the new battery. The Board have also excluded £230. 17s. 6d., interest on stock previous to receipt of loan, as they consider that this cannot properly be paid out of borrowed money. The works for which the previous loan was sanctioned had cost £7,069 in excess of estimate, and £34,088 further had been expended upon extensions in anticipation of the Board's sanction. The Board, therefore, regard the action of the Council in this matter as most unsatisfactory.

The estimates of the Electricity committee for the year ending March 31, 1901, were submitted to the Corporation last week and approved. The income is estimated at £18,233, and the expenditure at £17,277. There was a deficit on last year's working of nearly £300, caused mainly by the increased price of coal.

Stockport.—An inquiry was held last week into the application of the Corporation to borrow £23,468 for electric lighting extensions. The loan is chiefly required for new feeders. There was no opposition.

Sudbury.—An inquiry into the application of the Council to borrow £650 for the electric lighting of the Wents estate was held on Wednesday. The consulting engineer (Mr. W. C. C. Hawtayne) said that the bill confirming the Council's provisional order had already passed through the House of Commons. The scheme really formed portion of a larger scheme for electric lighting. The cost of lighting would be a shade under 2d. per unit; the total annual cost would be about £47; 2d. per unit would be equivalent to 1s. a thousand for gas. Opposition was offered by the local gas company.

Sunderland.—An inquiry was held on Tuesday into the application of the Corporation to borrow £4,500 for the purchase of land for erecting a new generating station. The town clerk (Mr. F. M. Bowey) and the borough electrical engineer (Mr. John F. C. Snell) explained that in consequence of the present station in Dunning-street being taxed to its utmost capacity, and as the demand for current continued to increase, it had been decided to erect a new station in Hylton-road. There was no opposition.

Sydney (N.S.W.).—The City Council have adopted an electric lighting scheme prepared by Major P. Cardew (Messrs. Preece and Cardew) and estimated to cost about £138,000. In his report Major Cardew states that an immense amount of money has been wasted in England by starting electric supply on an insufficient basis owing to the desire to keep down initial capital expenditure. The private supply at Sydney would probably be equal to 600,000 units per annum for the city alone, and after five years the public and private supply should reach 4,000,000 units a year. The cost is estimated as under:—Mains and street work, £60,000; generating plant, £50,000; buildings, &c., £25,000; wiring and fitting markets, &c., £3,000. Allowing for contingencies the expenditure necessary will be about £150,000. Major Cardew anticipates that after the second year the undertaking will become profit-earning. After the fifth year the profit will be considerable, even with a reduction of the price to 3½d. per unit. Messrs. Preece and Cardew have been instructed by the Council to prepare plans and specifications and invite tenders for carrying out the work.

Wolverhampton.—The Corporation have received sanction to borrow £1,730 for electric lighting extensions.

Workhouse Lighting.—The Holborn (London) Guardians on Wednesday adopted the report of their consulting engineer, Mr. James Enright, recommending the installation of the requisite plant and machinery for the electric lighting of the City-road Workhouse, at an estimated total capital outlay of £6,930. Mr. Enright was instructed to prepare plans and specification for the carrying out of the work at a total cost of £7,623. It was stated the cost of maintenance, repayment of loan, &c., would be about £1,000 a year, and the present gas bill amounted to nearly this sum.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

Durban (Natal) Corporation invite tenders for (*a*) the supply, delivery and erection of the overhead equipment for about 16 miles of equivalent single track, including poles, overhead trolley wire, distribution boxes, &c.; (*b*) the supply, delivery and erection of 22 double-deck motor cars complete; (*c*) the supply and erection of electricity generating plant, including three 250 kw. direct-coupled generators, boilers, condensers, cooling tower, switchboard, &c. Further particulars are set out in an advertisement, and specifications may be obtained from the agents to the Corporation (Messrs. Webster, Steel and Co.), 5, East India-avenue, Leadenhall-street, London, E.C., after 29th inst. Tenders in duplicate must be delivered to the agents by June 29, or to the town clerk of Durban by mail delivery on or about Monday, July 23.

The Provost, Magistrates, and Commissioners of the burgh of *Partick* invite tenders for the construction, supply, and erection of a dust destructor, with furnaces, flues, water-tube boilers, economiser, fans, and forced-draught furnaces. Specification, &c., can be obtained on and after Tuesday next, at the offices of Mr. Jas. Donaldson, town clerk, 97, West Regent-street, Glasgow, and a copy of the specification can be inspected at (but not obtained from) the offices of the engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, Westminster, S.W. An advertisement elsewhere gives further particulars, and tenders must be sent in to Mr. Donaldson by noon of Friday, June 8.

Leeds Lighting committee invite tenders for two or three 630 kw. two-phase generators and one or two sets of surface condensing plant Tenders to town clerk (Mr. W. J. Jeeves) by 10 a.m. of 28th inst.

Great Grimsby Corporation invite tenders for the supply and delivery of arc lamp posts and brackets. Specifications may be obtained from the town clerk (Mr. W. Grange), St. Mary's Gate, Grimsby. Specifications can also be seen at (but not obtained from) the office of the consulting engineer (Prof. Alex. B. W. Kennedy), 17, Victoria-street, London, S.W. An advertisement contains additional particulars. Tenders must be delivered at Mr. Grange's office by June 1.

Great Grimsby Corporation also invite tenders for the supply and delivery of electricity meters. Further particulars are set out in an advertisement, and tenders must be delivered at the offices of the town clerk (Mr. W. Grange) by June 1.

South London Electric Supply Corporation invite tenders for a complete installation of 3,000 lights on the premises of 500 consumers in any part of the company's area of supply, and also for the installation of two arc lights on the premises of any consumer in the same area. Specifications may be obtained from the secretary (Mr. H. H. Boyer), 54, Bengeworth-road, Loughborough Junction, London, S.E., and tenders must be in by Saturday, June 2. See advertisement.

Newcastle-upon-Tyne Tramways committee invite tenders for switchboards, underground feeders, and pumping apparatus. An advertisement contains additional particulars, and tenders for switchboards and feeders must be sent to the town clerk (Mr. Hill Motum) by 25th inst., and for the pumping apparatus by June 1. Specification and forms of tender can be obtained after 16th inst. from the consulting engineer, Mr. Chas. Hopkinson (Messrs. Hopkinson and Talbot), 26, Victoria-street, London, S.W.

Bradford Corporation invite tenders for the supply and delivery (for 12 months) of enclosed electric motors of 4½ H.P., 7 H.P., and 10 H.P. Specification, &c., may be obtained from the city electrical engineer (Mr. R. A. Chattock). Further particulars are given in an advertisement, and tenders must be sent to the town clerk (Mr. Frederick Stevens). Town Hall, Bradford on or before 24th inst.

Bradford Corporation also require tenders for the construction and delivery of two steam engines and two 1,000 kw. dynamos. Specifications may be obtained from the city electrical engineer (Mr. R. A. Chattock), and tenders must be delivered to the town clerk (Mr. Frederick Stevens), Town Hall, Bradford, on or before 24th inst. An advertisement gives further particulars.

Bradford Corporation require tenders for coal-conveying apparatus, hoppers and ash-conveying apparatus for their Valley-road electricity works. Specifications may be obtained from the city electrical engineer (Mr. R. A. Chattock). Tenders must be sent to the town clerk (Mr. Frederick Stevens) by 31st inst. See advertisement.

Fulham (London) Vestry require tenders for the wiring of their electric lighting works. Specifications, &c., can be obtained at the offices of Mr. F. Hastings Medhurst, B.Sc., 13, Victoria-street, London, S.W., and tenders must be sent to Mr. W. J. H. Denselow, Clerk to the Vestry, Town Hall, Walham Green, S.W., by Monday, June 4. An advertisement contains further particulars.

Sutton Coldfield Corporation invite tenders for the supply and erection of electricity generating plant, particulars of which are set out in an advertisement. Specification may be obtained (after 24th inst.) at the offices of the town clerk (Mr. Thos. V. Holbeche). The contracts will be carried out in accordance with the plans and specification of the consulting engineer (Mr. W. C. C. Hawtayne), 9, Queen-street-place, London, E.C., from whom further information can be obtained after 24th inst. Tenders must be delivered to Mr. Holbeche before noon of June 21.

London County Council's Asylums committee invite tenders for the installation of electric lighting and power (except generating plant) and the installation of telephones, tell-tale clocks, fire alarms and call bells at the Horton Asylum, near Epsom, Surrey. Further particulars are set out in an advertisement, and specification can be obtained from the clerk (Mr. R. W. Partridge) after 21st inst. Tenders must be delivered to the committee, 6, Waterloo-place, S.W., by 10 a.m., Saturday June 16.

Dundee Town Council require tenders for the overhead equipment of four electric tramway routes particulars of which are set out in an advertisement. Specifications, &c., may be obtained from the city electrical engineer (Mr. Walter H. Tittensor), and tenders must be lodged with the town clerk (Sir Thomas Thornton, LL.D.), City Chambers, Dundee, by 31st inst.

Digitized by Google

Dundee Town Council invite tenders for supply of copper bonds. Specifications, &c., may be obtained from the city electrical engineer (Mr. Walter H. Tittensor), Dudhope Crescent-road, and tenders must be lodged with the town clerk (Sir Thomas Thornton, LL.D.), City Chambers, Dundee, by 22nd inst. An advertisement contains additional particulars.

Dundee Gas Commissioners invite tenders for small coal and electricity meters. Specifications from the city electrical engineer (Mr. Walter H. Tittensor), Dudhope Crescent-road, and tenders must be delivered to the town clerk (Sir Thomas Thornton, LL.D.), City Chambers, Dundee, by 31st inst. See advertisement.

Devonport Corporation require tenders for the supply, delivery and laying of electric light and traction feeders, distributors, boxes, &c., in connection with the scheme of electricity supply for Devonport and East Stonehouse. Specification may be obtained from the borough electrical engineer (Mr. Charles Furness), Technical School, Devonport, and further particulars are set out in an advertisement. Tenders must be sent to the town clerk (Mr. A. B. Pilling) by 5 p.m. of 25th inst.

Walthamstow District Council invite tenders for the supply and erection of arc lamp posts and accessories and glow lamps on posts and on existing gas standards. Tenders to clerk (Mr. E. J. Gowen), Town Hall, Walthamstow, by 5 p.m. 29th inst.

Walthamstow District Council also invite tenders for fire alarms, wire, &c. Tenders to clerk before 5 p m., 25th inst.

Southampton Corporation invite tenders for a water-tube boiler with steam and other pipes and sundry ironwork. Tenders to town clerk (Mr. R. R. Linthorne) by 28th inst.

Bridgwater Town Council invite tenders for the supply and erection of electricity generating plant. Tenders to town clerk (Mr. W. T. Baker) before 3 p.m. on June 7th.

Crewe Town Council seek tenders for the supply and laying of about 25,000 yards of three-core cable for street lighting extensions, and the supply of upwards of 500 lamp holders and reflectors for adopting the existing lamp-posts for electric light. Tender to Mr. F. Cooke, town clerk by May 26.

Glasgow Corporation invite tenders for the supply of two sets of switchboards and instruments for 4,000 amperes each. Tenders to town clerk (Sir J. D. Marwick) before10 a.m., June 12.

Farnworth District Council require tenders for the erection of electricity station buildings. Tenders by 30th inst.

Wolverhampton Tramways committee invite tenders for the construction of nearly two miles of tramway. Tenders by June 26.

Worksop District Council require tenders for electricity generating plant. Tenders to clerk by 23rd inst.

Corporation of *London* Streets committee invite tenders for the supply on hire of electrically-driven dust carts. Tenders to town clerk (Sir John B. Monckton), Guildhall, E.C., by June 1.

Tenders are invited for wiring the *Leeds* Central Fire Station. Tenders to town clerk by 28th inst.

Bradford Corporation invite tenders for castings, forgings and turned work required for slipper brakes for electric tramcars. Tenders to town clerk by 19th inst.

Vladivostock (Siberia) Municipal Council invite tenders for the concession for erecting electricity works and for constructing an electric tramway.

Tenders are invited for the concession (which has already been applied for) for the construction and equipment of an electric tramway from the Puerta de Hierra (*Madrid*) to Aravaco and Pozuelo. Tenderers are required to tender in the first instance on the basis of a reduction on passenger fares set out in a schedule to the specification. The contract will be awarded on July 7.

Norwegian State Railways Administration invite tenders until 23rd inst. for telegraph and telephone materials.

The Council of *St. Gilles-lez-Bruxelles* (Belgium) invite tenders for an electricity supply installation for part of its territory. Conditions (for 3fr.) from 14, Parois St. Gilles, St. Gilles, and tenders to Mayor, before 2 o'clock of Sept. 19.

TENDERS RECEIVED AND ACCEPTED.

The Shoreditch (London) Vestry have received the following tenders for the supply of electric cables :—

British Insulated Wire Co. (*accepted*)	£582 14 8	W. T. Henley's Co.	£634 0 0
Siemens Bros. and Co.	655 2 3	W. T. Glover and Co.	598 5 10

The following tenders have also been received by the Vestry for the supply of feeder panels for switchboard :—

Electric Construction Co. (*accepted*)	£455	Crompton and Co.	£555
Brush Co.	716	General Electric Co.	497
Nalder Bros. and Thompson	575	Evered and Co.	457
		Verity's (Ltd.)	456

Plymouth Corporation have accepted the tender of Messrs. R. W. Blackwell and Co. for the supply and erection of the overhead electric equipment of the Compton electric tramway route at £3,433. The British Insulated Wire Co.'s tender at £3,270 was recommended for acceptance by the Tramways committee, but an amendment by Mr. Radford that Messrs. Blackwell and Co.'s tender be accepted was carried at the Council meeting on Wednesday.

The tender of Messrs. Fisher and Allison has been accepted for the electric lighting of the Doncaster Corn Exchange.

The Durban (Natal) Corporation have accepted the tender of Messrs. J. Hubert Davies & Spain, Johannesburg and East London, for the supply of steel rails and laying 15 miles of tramway track for electric traction (exclusive of Australian hardwood stringers) at £30,286.

Cheltenham Council have accepted the tender of Messrs. Siemens Bros. and Co. for a continuous-current dynamo at £480, and that of Messrs. Witting Bros. and Co. for a traction dynamo at £420.

APPOINTMENTS VACANT AND FILLED.

An assistant lecturer and demonstrator in electrical engineering is required for the University College of North Wales, Bangor. Applications to the secretary and registrar (Mr. J. Lloyd, M.A.), not later than June 9. See advertisement.

The chief electrical engineer of the Redditch District Council has a vacancy for three pupils. Particulars from Mr. W. J. Ferguson. See advertisement.

Southport Corporation require a manager for their tramway Further particulars are given in an advertisement, and applications must be sent to the town clerk (Mr. J. Ernest Jarratt), Town Hall, Southport, by 28th inst.

Cardiff Corporation invite applications for the appointment of a tramways electrical engineer, at a commencing salary of £500 per annum. Application to town clerk (Mr. J. L. Wheatley), Town Hall, Cardiff, by June 1. An advertisement contains additional particulars.

There is a vacancy for an assistant superintendent in the telegraph department of the Government of India. Further particulars may be obtained on application to the India Office, and applications should be sent to the Secretary, Public Works Department, India Office, Whitehall, London, S.W., by June 30. See advertisement.

A head-master is required for the Industrial School, Lucknow, India. Some additional information is given in an advertisement. Forms of application and further particulars can be obtained from the Director-General of Stores, India Office, Whitehall, London, S.W.

A lecturer is to be appointed at Cambridge, in succession to Mr. W. N. Shaw, F.R.S., lecturer in experimental physics. Applications are to be sent to the Vice-Chancellor by May 19.

Mr. William Paul, of the engineer's office of the City and South London Railway, has been appointed mechanical draughtsman to the electricity department of the Islington Vestry.

BUSINESS NOTICES.

The registered offices of Marconi's Wireless Telegraph Co. (Ltd.) have been removed from 28, Mark-lane, E.C., to 18, Finch-lane, Threadneedle-street, London, E.C.

Messrs. A. W. Flowerdew and W. M. Hunt (trading as Flowerdew and Hunt), electricians, &c., 42, Bridlesmithgate, Nottingham, have dissolved partnership. Debts by Mr. Flowerdew.

BANKRUPTCIES, LIQUIDATIONS, &c.

A first and final dividend of 5s. 7d. is payable at the O.R.'s, 31, Silver-street, Lincoln, in the bankruptcy of W. H. Bowman, electrical engineer, &c., lately trading at Heaton-street, Gainsborough.

The Doe Portable Electric Light and Power Syndicate (Ltd.) is to be wound up voluntarily, with a view to reconstruction. Mr. J. E. Ward, 122, Cannon-street, London, E.C., is liquidator.

A meeting of the Phœbus Electric Solder and Electric Soldering Fluid Co. (Ltd.) will be held at 52, Ayton-road, Stockwell, London, S.W., on June 18, to receive an account of the winding-up. Mr. S. Shortman is liquidator.

A meeting of the Nalder and Harrison Construction Syndicate (Ltd) will be held at 19, Queen Victoria-street, London, E.C., on June 16, to receive an account of the winding-up. Messrs. J. A. McMullen and N. Frank Nalder are liquidators.

Claims against the Perfect Arc Lamp and Accessories Co. (Ltd.) are to be sent by June 11 to the liquidator, Mr. S. H. Lee, 85, Gracechurch-street, London, E.C.

Gordon Webber, electrical and mechanical engineer, trading as G. Webber and Co., 101, Mount-pleasant, Liverpool, and at Leigh, has executed a deed of arrangement. Liabilities £173. 4s. 8d., assets £92. 2s. 10d. Mr. S. Jude, 14, North John-street, Liverpool, is trustee.

Thomas T. Markham, electric light contractor, 7, Warwick-court, Holborn, W.C., and Grove road, South Tottenham, N. London, has executed a deed of arrangement. Liabilities £215. 8s. 9d., assets £130. 7s. 10d.

Digitized by Google

Plant for Sale.—Messrs. Cornelius and Boulter, the Promenade, Cheltenham, announce in an advertisement the sale by auction on 22nd inst. at noon, of the contents (including electric lighting plant and machinery) of the Assembly Rooms, Cheltenham. Catalogues, &c., from the auctioneers.

Some electric lighting plant (including a Fielding and Platt's gas engine and dynamo, switchboard and instruments, &c.) is advertised for sale in another column. Further particulars from Mr. J. A. McMullen, M.I.E.E., 17, Gracechurch, London, E.C.

Leeds Corporation invite tenders for the purchase of electric tramways plant. Further particulars of the plant, which may be inspected on application to the engineer-in-charge, are set out in an advertisement. All further information may be obtained from the consulting engineers (Messrs. Hopkinsons and Talbot), 26, Victoria-street, London, S.W. Tenders to town clerk's office, by 23rd inst.

Mr. Robert Feather, Craven Bank Chambers, Market-street, Bradford, has received instructions from the representative of the late Mr. B. U. Moore, to sell by auction on Tuesday, 29th inst., the machinery and plant, at 197, Sunbridge-road, Bradford. An advertisement contains further particulars, and catalogues may be obtained from Mr. Feather.

Messrs. Firth and Wright will sell by auction on Monday next, at 12 noon prompt, a large quantity of electrical, mechanical, and chemical manufacturing plant, &c., at Upper Lane Mills, opposite Cleckheaton station. Catalogues can be had of Messrs. Butterfield and Hartman, accountants, 2, Darley-street, Bradford, and of the auctioneers, Cleckheaton and Heckmondwike.

Business for Sale.—An electrical engineering business is advertised for sale in another column. The works are conveniently situated within 10 minutes of London.

A Large Belt.—Messrs. Balderston and Co., 201, St. Vincent-street, Glasgow, have recently specially manufactured for Messrs. Crosses and Winkworth, Bolton, a Hoyt double leather belt 147ft. long and 45½in. wide, the nett weight being 1,209lb., or 17½oz. per sq. ft. of single surface. The belt required the exact centres of 70 butts in its manufacture. At the speed it is intended to run the belt will transmit 528 H.P.

E. P. S. Cells.—To illustrate the electrical Power Storage Co.'s exhibit at Paris (stand No. 506, Group V.) a pamphlet has been issued describing and illustrating different types of E. P. S. cells, and giving a brief history of the company which is the oldest and premier company devoted entirely to the manufacture of electric accumulators or storage batteries. The pamphlet will be found serviceable by non-technical visitors to the Exhibition, and the information regarding accumulators and their uses which is here given will be read with general interest. It is singular that in this pamphlet as in so many other places Lord Kelvin's surname is spelt with a "p." The cover of the pamphlet might with advantage be strengthened.

"Maxim" Incandescent Lamps.—A neat list of "Maxim" incandescent lamps is now ready and obtainable by the trade from the Hiram S. Maxim Electrical Corporation (Ltd.), 44, Gillingham-street, Victoria, London, S.W. High and low voltage lamps of from 3 c.p. to 500 c.p. are listed, and a variety of shapes and designs of lamps of this company's make are illustrated.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from May 9 to May 15, with the ports of destination:—

Africa—Alexandria, £38; Cape Town, £45; Durban, £423 (including £101 telegraph material); East London, £82; Quilimane, £62; Zanzibar, £71. *Argentina*—Buenos Ayres, £549 (including £312 telegraph material). *Australasia*—Adelaide, £96; Auckland, £35; Freemantle, £56; Melbourne, £136; Otago, £70; Sydney, £2,404 (including £89 telegraph material); Wellington, £242. *Azores*—£1,151 (telegraph material). *Burma*—Rangoon, £352. *Ceylon*—Colombo, £152. *Chili*—Boca, £385 (including £155 telegraph material). *Denmark*—Copenhagen, £28 (telegraph wire). *France*—Boulogne, £36. *Germany*—Hamburg, £700 (including £400 telegraph material). *Holland*—Amsterdam, £275; Flushing, £9. *Hong Kong*, £16. *India*—Bombay, £223; Calcutta, £1,101 (including £355 telegraph wire); Karachi, £240. *Japan*—Kobe, £745 (telegraph cable); Yokohama, £585. *Malta*, £135. *Spain*—Barcelona, £128 (including £102 telegraph wire). *Sweden*—Stockholm, £88 (telegraph material). Total £10,662, against £15,197 in the corresponding week last year (May 10 to May 16).

CITY OF LONDON ELECTRIC LIGHTING CONTRACTS.—Mr. J. W. Martin, who has vigorously criticised the action of the City Corporation in repudiating the validity of its contracts with the Brush Co. and Messrs. Laing, Wharton and Down (subsequently taken over by the City of London Electric Lighting Co.), points out, in regard to Mr. Justice Farwell's judgment establishing the validity of the contracts, that had the decision been reversed, the value of City of London Corporation securities as a safe investment would have been jeopardised. Mr. Martin estimates that the Corporation will have to issue a new loan of £2,000,000 to cover its liabilities to the City of London Co.

COMPANIES' MEETINGS AND REPORTS.

New General Traction Co. (Ltd.).

The fourth annual general meeting was held on Wednesday, under the presidency of Capt. FRANCIS PAVY.

The CHAIRMAN stated that four years ago the undertaking was a very small one—certainly as regarded capital. It only had £50,000 of preference capital, and the ordinary capital, which they now saw in the balance-sheet under the item of goodwill. He was approached because the amount of work in hand required further funds, and, believing it to be extremely good business, he and some of his friends joined the company. During the period in which they had been connected with it they had been enabled to put in an additional £200,000, and someone, he thought, would be required to provide something more before the works were finished, and the full benefit was reaped of what they had been doing. He thought it might be said that they had done very well during the period in question He thought that the shareholders should be satisfied with the balance-sheet. After deducting £6,116 for general expenses, salaries, &c., chargeable against revenue, they were left with a balance of gross profits of £76,299, which was increased by the amount brought forward to £82,512. During the year the directors had raised £100,000 of additional preference capital, making it £250,000. The cost of raising this was £281, which had been written off, and thus they were left with a disposable balance of £82,20. A dividend on the 6 per cent. preference shares (absorbing £13,487) had been distributed, which the shareholders were now asked to confirm, and deducting this, a balance remained of £68,743. Of this they proposed to appropriate £10,769 to reserve against goodwill, this making, with a further £2,230 from profit and loss, the sum placed against goodwill account, £13,000. The directors had commenced a reserve fund, to which they had placed £20,000, and this left them with a balance of £37,030 to start the new year. These figures were all based on the price at which the shares of the tramway undertakings in which the company were interested were taken, and this was at par. They had about £100,000 in the Coventry Electric Tramways, £165,000 in the Norwich Electric Tramways, £21,000 in the Douglas Southern Electric Tramways, £1,973 in the Light Railways Syndicate, and £76,000 in the Philadelphia, Morton, and Swarthmore Street Railway. He concluded by moving the adoption of the report and accounts.

Baron EMILE B. D'ERLANGER seconded the resolution, which was carried.

The dividend on the preference shares was sanctioned, and the proceedings closed with a vote of thanks to the chairman and directors.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Jan. 25, 1900). Price of silver 27 11/16d. per oz. (May 17). Consols (2¾ per cent.) 101⅛—101⅜ for money, 101⅜—101½ for account; 2½ per cent. 98¼—98⅜ (May 17). Stock Exchange Settling Day: Consols, June 1; Stocks and Shares Continuation Days, May 29 and June 12; Ticket Days, May 30 and June 13; Pay Days, May 31 and June 14; Mining Share Carry-over Days, May 28 and June 11.

CHISLEHURST ELECTRIC LIGHTING CO. (LTD.)—The annual report states that the supply of current was commenced in Feb., 1899, with an equivalent of 806 8 c.p. lamps connected, and this number had increased at the end of the year to 4,017. The net profit (£83. 1s. 7d.) has been carried forward.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH CO. (LTD.)—With the view to partly meeting the expenditure necessary in connection with the new Australian cable to be laid by this company, the directors have decided to issue to the shareholders the unused balance of 50,000 ordinary shares of £10 each at a premium of £3 per share. For this purpose the share register is closed until May 19.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER CO. (LTD.)—The report of the directors for the past year states that there is a credit balance on the general account of £6,864, of which £5,663 has been paid as interim dividend. The profit on the Ramsey section of £2,415 is insufficient to meet the debenture charges of £2,600. The auditors (Messrs. Aldred and Co.) point out that whereas the capital expenditure has been £518,000, only £366,000 has been raised by shares and debentures, the balance being accounts owing, bills payable and bank overdrafts. Messrs. Turquand, Young and Co. are to report on the position of the company.

JAMES HINKS AND SON.—The net profits for the year ended March 31 amounted to £10,991. 18s. 9d., and a final dividend of 10 per cent. per annum was declared.

KENSINGTON AND NOTTING HILL ELECTRIC LIGHTING.—Applications are invited for an issue of £100,000 4 per cent. debenture stock by the Kensington and Knightsbridge Electric Lighting Co. (Ltd.) and the Notting Hill Electric Lighting Co. (Ltd.), the money being required for the joint station of these companies, authorised under the Kensington and Notting Hill Electric Lighting Companies' Act of 1899. The list closes this day (Friday).

MIX AND GENEST, LTD. (BERLIN).—The general meeting of this company was held on Saturday. The directors' report stated that the gross profit was £30,090, which, after making provision for depreciation on plant, tools, and buildings (£11,800), left a net profit of £18,290, out of which a dividend at the rate of 12 per cent. has been declared. The progress of the company is attributed mainly to the large extension of the

Digitized by Google

telephone system in Germany. The directors anticipate that the requirements of the German Government will be still larger in the future on account of the adoption of the metallic circuit system. A further impetus has been given to the telephone industry by the German General Post Office allowing subscribers' private installations to be connected to the Government telephone system, free of charge, the only stipulation being that the instruments used on such private installations should be equal in quality to those used by the Government.

MOTOR GESELLSCHAFT FUR ANGEWANDTE ELECTRICITAT.—This company which is closely allied to Messrs. Brown, Boveri and Co., ha declared a dividend of 7 per cent. for the past year.

STOCK EXCHANGE NOTICES.—Tuesday last was appointed a special settling day for £300,000 5 per cent. first mortgage debenture stock of the *British Aluminium Co.* (*Ltd.*), and the securities have been ordered to be quoted in the official list. Wednesday, 23rd inst., has been appointed a special settling day in the further issue of 7,532 £3 full-paid ordinary shares (Nos. 46,419 to 54,000) of *Crompton and Co.* (*Ltd.*), and 81,092 £5 (£3. 10s. paid) and 18,908 fully-paid ordinary shares (within Nos. 490,001 and 590,000) and fully and partly paid provisional certificates for £5.0,000 4 per cent. debenture stock of the *National Telephone Co.* (*Ltd.*). The Stock Exchange Committee has also been asked to appoint a special settling day in 25,000 vendor's 7 per cent. cumulative preference £1 (fully-paid) shares (Nos. 115,001 to 140,000) of the *Nernst Electric Light Co.* (*Ltd.*), and to allow the further issue of 12,500 6 per cent. cumulative preference £5 fully-paid shares (Nos. 27,501 to 40,000) of the *British Insulated Wire Co.* (*Ltd.*) to be quoted in the official list. Application has also been made to the Committee to appoint a special settling day in and to grant a quotation to 7,000 5 per cent. cumulative £10 fully-paid preference shares of the *Alliance Electrical Co.* (*Ltd.*), and to allow the further issue of 20,000 6 per cent. cumulative £5 fully-paid preference shares (Nos. 54,001 to 74,000) of the *New General Traction Co.* (*Ltd.*) to be quoted in the official list.

WEST INDIA AND PANAMA TELEGRAPH CO. (LTD.)—The profits of this company for the half-year ended Dec. 31, 1899, being insufficient to provide the preference dividends, the directors have decided to withdraw the sum required from reserve, and recommend on this occasion the payment of the usual dividends on the cumulative preference shares, and one shilling per share on the ordinary shares.

WYCOMBE ELECTRIC LIGHT AND POWER CO. (LTD.)—The annual meeting was recently held at High Wycombe. At the end of the year the equivalent of 7,636 8 c.p. lamps (including about 130 H.P. in motors) were connected, and since the beginning of the current year 4,225 further lamps had been applied for. The net profit was £438. 18s. 4d. After paying a dividend of 2½ per cent. upon the ordinary shares, and applying £144. 13s. 9d. in paying Parliamentary expenses, the balance (£230. 13s. 4d.) was carried forward. At the end of the last quarter the connections were equivalent to 10,279, and about 2,170 more were awaiting connection. The report and accounts were adopted.

NOTES.

SIR E. SASSOON, who in the House of Commons on Wednesday last moved that an inquiry should be held into the commercial and strategic defects of our Imperial telegraphic communication, showed a certain familiarity with the more obvious facts of the subject. He quite failed, however, to grasp the point that the growth of traffic with a given place must finally have a greater effect than even distance in determining the tariff. Although the population of India, for instance, enormously outnumbers that of Australasia, the telegraphic traffic of the former has been practically stationary or retrograde year by year, while that of the latter has continuously increased and has always responded to reductions of rate in a way that India has never done. In comparing internal with international tariffs he failed to perceive that there are sacrifices—to secure uniformity or for other reasons—which a State may make on telegrams within its own territory, but which are not legitimate or even possible where messages pass over the lines of several countries. Sir E. SASSOON raised a laugh by pointing out that States like Luxemburg which possess no cables at all, have an equal vote with Great Britain in international telegraphic conferences; but international messages transit land lines as well as cables, and he did not explain how Sovereign States could be induced to take part in such a congress on any other basis than that of equality, nor that the colonies of Great Britain possess votes. Of course, in practice, on these occasions votes, which are weighed as well as counted, have no binding effect until the resultant convention is accepted and confirmed by the high-contracting parties. Further, it may interest him to know that the companies which own the cables have no vote at all.

SIR C. DILKE, who seconded the resolution, confined his remarks to the strategic aspect of the question. He expressed the view held by those entitled to speak with some authority on the matter—the late Sir JAMES ANDERSON, for instance—that while many of the cables might be cut, were Great Britain at war with a Continental Power, it would be impossible in practice to interrupt all the alternative routes simultaneously. And, of course, for this purpose an alternative route is one, no matter how roundabout, by which communication can be effected. He instanced a message between the metropolis and Cornwall, viâ Malta. In another case communication was effected between Land's End and London, by way of New York. His point as to the importance of the deep-sea landing of cables is not so obvious. The difficulty of interrupting a cable midway in any ordinary depth is not much greater (but rather less, so far as prevention is concerned), than near the landing-place. It is no good to shut one's eyes to facts—cables every day are repaired with little trouble, and they can be broken with even less difficulty. For strategic purposes in war, the only remedies are multiplicity of routes, cables laid secretly, strict silence as to sections interrupted, and the probable discovery of methods of working across "breaks."

As to the State purchase of submarine lines, no one seems to have thought out the difficulty respecting the way in which our Government is to get permission to work cables landing on the coasts of foreign Powers. Sir JOHN PENDER used to say, "Cables have no politics." In private hands they are cosmopolitan and secrecy-preserving, but are foreign nations likely to believe they would continue to be so in the hands of the British Government? Continental jealousy of British-owned cables is very great. What it would be if they were worked by our Government no mortal can conceive. If the cable companies had not existed they would probably have had to be invented.

MR. HANBURY admittedly made an able speech in winding up the debate, and had little difficulty in replying to the arguments which had been advanced. He pointed out that cheap telegrams and strategic cables were inconsistent with

Digitized by Google

each other, because the former depended upon tapping every source of traffic at foreign ports, while the latter must avoid non-British territory as well as all English stations which could not easily be defended. He showed that most of the existing cables followed the main routes of trade, being, therefore, more easily capable of protection by our fleet; and that if the matter were left in the hands of the Government they would endeavour to meet the views of those who wished for cheap telegrams as well as of those who urged the importance of strategic cables. There is much to be said for the Government decision in favour of a departmental as against a parliamentary enquiry. National enterprise and foresight have been allowed a long start in establishing a network of cables all over the world, and—there is such a thing as letting well alone.

ROYAL birthday honours this year are notably deficient in the recognition of science, doubtless because in war times the arts of peace may reasonably be expected to wait. With the exception of DAVID GILL, the eminent Astronomer-Royal at the Cape, who has received a K.C.B., and Prof. T. E. THORPE, who has received a C.B., the name of no distinguished scientist appears on the list of honours. The electrical profession, however, will join with his numerous other friends in congratulating Sir RICHARD WEBSTER on his elevation to the peerage. In the office of Attorney-General, Sir RICHARD has frequently taken a leading part in events fraught with much importance to that profession and its industries.

WHILE it must be admitted that the scheme for an express mono-rail between Liverpool and Manchester appeared to be defective in several important details, it is impossible not to regret that this novel system of traction has received so serious a check as is implied in the rejection of the scheme by the Select Committee on Tuesday. On the whole, however, the Committee was quite justified in refusing to sanction any of Her Majesty's subjects being carried through mid-air at over 100 miles an hour, until such time as the safety of this feat is better guaranteed. We suggest that the possibilities of this high-speed system of traction might first be tested by the construction of a line purely for light parcel and mail traffic. It would then very soon be seen whether the system is a safe one for passenger traffic.

DURING the last few weeks there have been several cases of serious disagreement between municipal electrical engineers and their committees. In some instances, the duties and powers of the municipal engineer do not seem to be fully defined, with the result that there have been cases of this official exceeding the proper limits of his office, and on the other hand examples of undue interference on the part of the electric lighting committee. It would be well within the province of the Municipal Electrical Association to express an opinion as to how far the control of a municipal electricity department should be vested in the engineer; for although a report dealing with such a matter could in no way be binding the electrical engineer or his employers, it might tend to promote a unanimity of ideas on certain matters of professional etiquette which would go far to improve the *status* of the municipal electrical engineer, and to prevent many disputes of the nature of those to which we have alluded.

THE annual report of the Comptroller-General of Patents is always an interesting document. Its mass of statistical information enables deductions to be drawn as to the relative inventiveness during the year and the directions in which this inventiveness has extended. The report for the year 1899 exhibits a peculiar phenomenon, viz., that the number of applications for patents has steadily diminished during the last two years, having reached its maximum (30,952) in 1897, and fallen in 1899 to only 25,786. In commenting on the report for 1897 we called attention to the fact that although an increase in the total number of patents applied for that year was apparent, the quantitative inventiveness of Great Britain and its colonies had slightly decreased, and it is apparent that this decrease has continued. A diminution is apparent not only in the number of patents applied for, but also in the number of complete patents sealed; while on the other hand, the value at which patents are held does not appear to have diminished, for there were more 13 and 14-year old patents last year than in previous years, showing that it has been found worth while to pay the fees to maintain more patents for their full life than hitherto.

DETAILED figures as to the number of inventions in the various classes each year up to 1898 are given, and show some curious results. An effect of the Workman's Compensation Act was to increase the number of inventions for guards for preventing accidents in working circular saws. The interest in penny-in-the-slot machines is reviving, and inventions continue to flow with greater frequency into the classes "Dynamo-Electric Generators," "Electric Lamps," and "Electric Telegraphs (including Telephones and Phonographs)," and "Steam Engines." "Galvanic Batteries," however, are being invented at a slower rate than heretofore. During 1899 the accidents to passengers on trolley cars have resulted in several applications for patents for safety arrangements, and in non-electrical matters it is interesting to note that recent legislation and threatened legislation has promoted invention in the matter of seats for shop assistants, and of automatic couplings.

WE are able to recall but few instances where the microscope, an instrument of importance in so-called "natural science" researches, has been used with effect in physical investigation. Indeed, except as an auxiliary instrument for measuring the bore of a tube or the diameter of a wire, we believe it rarely finds a place among physical instruments. That physical science is the loser by the neglect of the microscope as an active agent of research was made evident in the course of Prof. J. A. EWING's admirable and lucid discourse at the Royal Institution, on Friday evening last, on "The Structure of Metals." This was an account of a series of experiments carried out during the past two years in Prof. EWING's laboratory at Cambridge, in conjunction with Mr. W. ROSENHAIN, on the structure of metals as revealed by a close inspection of the surfaces of metals which had been polished and lightly

Digitized by Google

etched, or subjected to other physical or mechanical processes, such as heating, tension or compression. The results obtained were presented to a large audience in a series of beautiful micro-photographs, some of which, as thrown on the screen, represented a magnification of 170,000 diameters, a striking testimony to the searching and penetrating nature of the camera, and to the great experimental skill exhibited by Mr. ROSENHAIN.

THE main portions of the lecture had already been communicated to the Royal Society, and were the subject of last year's Bakerian Lecture, a long abstract of which was given in *The Electrician* (Vol. XLIII., p. 239). It was there shown that every metal or alloy, either under normal or abnormal physical conditions revealed, when examined under the high power of a microscope, distinct granular, or even crystalline structure, which no subsequent treatment could eradicate permanently. However heterogeneous a body might appear to be, closer investigation revealed perfect homogeneity; there were found geometrical form and uniform design even in metals which, like lead, might have been carelessly assumed to have no form or definite structure at all. A metal might thus be compared to a platoon of infantry, which outwardly might have any form, or any kind of bounding line, yet internally and individually each member remained the same and resembled his fellow. The plasticity of metals, from which property its heterogeneity is generally assumed, was then explained by the slipping of the granular crystals more or less readily over each other. To carry the military illustration a step further, a battalion which was very mobile, the members of which were continually slipping by and in front of one another, might present the appearance of a disorganised rabble, yet a closer inspection would reveal that the individuality of the members was unimpaired.

THE entirely new features of Prof. EWING'S discourse lay principally in his account of the extension of their researches to the "growth" of these granular structures. If a metal, lead for example, be subjected to considerable compression, the surface revealed a somewhat irregular granular structure, the size of these granules being comparatively very small. In the course of a few months, weeks, or sometimes days, periods which are considerably diminished by the application of heat, these small granules gradually coalesce and increase considerably in size, and are then found to have again assumed the original crystalline structure of the untreated lead. The same effects were discovered in other metals. There is a suggestion of vitality about this growth which is not a little fascinating to the student, seeming to link more and more closely animate with inanimate matter. The explanation of this growth, which Prof. EWING attributed to his collaborator, Mr. ROSENHAIN, is not a little ingenious, and it must be admitted is, so far as it has yet been carried, borne out by the facts. Between the granules of any metal, however pure, is supposed to exist some amount of impurity; into this the small granules dissolve, forming with it a kind of "eutectic" alloy, from which they subsequently crystallise out again, increasing in size during the operation. Experimental confirmation of this hypothesis was found in the fact that across the surface of a cold-welded bar, whose contiguous surfaces had been very carefully cleaned, no such growth was possible, simply because the necessary impurity was not present. On spreading some impurity over these surfaces before they were brought into contact and welded together, the growth took place across the welded surface with perfect facility.

International Telephony.—Direct telephone communication has just been made available between Berlin and Basle.

Personal.—Prof. Ludwig Boltzmann, of Vienna, has been appointed to the chair of physics in the University of Leipzig.

Electrical Engineer (R. E.) Volunteers.—With the approval of the War Office the establishment of this corps is to be increased from four to seven companies.

The Identity of Argon.—In the last issue of the *Chemical News* Dr. T. L. Phipson describes some experiments which he has made on cyanogen gas after passing over red-hot iron nails in a glass tube. He concludes that the resulting gaseous body might be identical with argon, which would therefore be a *carbide of nitrogen* containing half the carbon contained in cyanogen.

Search-lights on the Suez Canal.—The Suez Canal Co. has decided that every vessel, before it can pass through the Suez Canal, must satisfy the company's agents at Port Said or at Suez that it has on board (1) at least one electric search light of sufficient power to illuminate the channel 4,000ft. ahead, and constructed so as to admit of rapid splitting up of the beam of rays into two separate segments, with a dark sector in the middle; and (2) with electric lights capable of lighting up a circular area 700ft. in diameter.

The Institution of Junior Engineers.—At a meeting of the Institution of Junior Engineers, held at the Westminster Palace Hotel on May 18th, a Paper was read by Mr. Charles H. E. Rush and Mr. Basil H. Joy on "A Short Review of the Motor Car Industry, Past and Present." The authors confined themselves to a description of oil-driven vehicles, other systems being only briefly alluded to. At the conclusion of the meeting it was announced that the summer meeting of the Institution would be held at Newcastle-on-Tyne on August 18th.

Institution of Electrical Engineers (Irish Section).—The official nominations of the members to be elected as committee of the Irish Section of the Institution of Electrical Engineers were announced at the ordinary meeting held on April 26 last. Owing to the short time during which they had occupied this position, the committee decided to submit themselves *in toto* for re-election. There having been no further nominations, as specified by the articles of association, the committee is duly elected. A list of the members was given in *The Electrician*, Vol. XLIV., p. 495, but one name, that of Mr. C. A. Burge, is to be added.

Extension of Canadian Water-Power Company.—The Chambly Power Co. is, says the *Electrical World* of New York, about to build a second dam across the Richelieu River, Quebec, about two miles above the present dam. This will, it is expected, serve the double purpose of preventing the formation of anchor ice at the lower dam, and of providing an additional 10,000 H.P. for transmission to Montreal, where it is pressingly required. At present the maximum load quite utilises all the current transmitted to Montreal, and it is anticipated that the additional power will be nearly all used up by the Montreal Electric Street Railway.

Telephone Service in Tokio.—The demand for telephonic communication in Tokio, Japan, is very strong, and the

Digitized by Google

supply is stated to be entirely inadequate to meet the demand. While there were at the end of February 5,645 subscribers, there were in addition 5,641 applicants waiting to be connected up. Extremely high prices are being paid to subscribers for a transfer of their instruments, and even for a transfer of an application made before June, 1897. The delay in receiving the necessary wire is responsible for this deadlock, but it is expected that 1,700 of these applicants will be connected up by June next.

Voltage and Current Recorder.—According to the *Electrical World* of New York, an interesting apparatus has been designed by Mr. F. W. Springer, of the University of Minnesota, for automatically recording current and voltage. It is a combination of a chronograph and Weston continuous-current instrument, and is stated to have given excellent results in a recent test on a 400 H.P. motor. The instrument records between 50 and 100 times per second, and uses up a strip of paper 90ft. long and 10in. wide per hour. It is expected that this instrument will be of considerable usefulness on street cars, enabling an accurate comparison of the power required in accelerating the cars under various conditions of track, loads, motors, speeds, &c., to be made. It will be useful also in supplying the variations of current and pressure on starting.

Glasgow International Exhibition, 1901.—Electricity is to be employed to a somewhat considerable extent in the International Exhibition to be opened at Glasgow next year. The buildings, which (including the permanent art gallery and museum) will cover an area of about 20 acres, will be lighted by Brockie-Pell arc lamps, decorative lighting, &c., being effected by means of incandescent lamps. In the handling of exhibits electric cranes will be used wherever necessary, and a special feature will be the driving of many of the exhibits by electric motors. We are requested to state that all applications for space must be lodged not later than the 30th inst. with the general manager (Mr. H. A. Hedley). To professional men the Glasgow Exhibition will be of special interest, inasmuch as many of the principal scientific bodies, including the British Association and the Institution of Mechanical Engineers, are to hold their annual meetings in connection with it.

Institution of Electrical Engineers.—As no other names have been proposed for the council for next session, the members nominated by the retiring council have been declared duly elected. The constitution of the new council is therefore that given in the list published in *The Electrician* of April 27, 1900, p. 3.

The Institution of Electrical Engineers (Manchester Section.—The incorporation of the Northern Society of Electrical Engineers with the Institution has already resulted in the addition of some 66 members to the roll of the Institution membership, and there are still about a dozen more names to be added. In mentioning this at the meeting of the Institution on May 17th, the President remarked that the hands of the Institution would thus be strengthened in and around the Manchester district, and a distinct debt of gratitude was owing to the Officers, Council, and Honorary Secretary of the Northern Society for the manner in which they had helped to smooth over difficulties which might have occurred in bringing to a conclusion these somewhat delicate negotiations. The names of the 66 new members were then read out by the Secretary.

The Vizzola Electric Power Works.—In view of the remarks made by Dr. S. P. Thompson at the conclusion of the discussion on Prof. George Forbes' Paper at the Institution of Electrical Engineers (*The Electrician*, May 18, p. 131), the following further particulars of the system are of interest. The "Società Lombardia per Distribuzione di Energia Elettrica" was formed in 1897 with a capital of £320,000, subsequently increased to £400,000, and obtained a concession from the Government on the River Ticino, at Vizzola, some miles below its issue from lake Maggiore. The works, as originally contemplated, were for the distribution of about 10,000 H.P., but since they were begun the sanction of the Government has been obtained to the construction of a movable dam across the river some distance higher up, which will enable the volume of water available to be increased and to be kept constant during all seasons of the year, so that the effective electrical horse-power would be increased to some 12,000 E.P. Although this dam has not been commenced, the works have been constructed on the basis of this larger power. Seven turbines have been erected, each coupled to a 1,650 kw. three-phase alternator, running at a pressure of 11,000 volts; and there are, in addition, two exciters driven by separate turbines, with a capacity of 145 kw. at 110 volts. The two smaller turbines, as well as five of the larger ones, have been made by the firm of Riva, Monneret and Co., of Milan. The other two are of German manufacture, as are also the dynamos and remainder of the electrical plant. It was originally intended to transmit this energy to Milan, which is 25 miles distant; but all has been disposed of, as Dr. Thompson has said, in several manufacturing towns closer to the works, viz., Gallarate, Busto, Arsizio, Legnano, and Sarsuno, which towns at present use some 10,000 H.P. of steam power. The average price at which the electrical power is to be supplied is £4. 4s. per kw. per annum for 12 hours' use per day, the price for 24 hours' use per day being only slightly greater.

The Institution of Electrical Engineers and the Paris Congress.—M. Mascart, the President of the Electrical Congress which is to be held in Paris in August, and to which the Institution is sending delegates, has addressed a letter to Dr. S. P. Thompson relating to contributions from English writers to be read at the Congress. Dr. Thompson read the following translation at the meeting of the Institution on May 18: "In order to facilitate discussions at the Electrical Congress we have thought that it might be useful to have a series of reports upon questions of present interest. Some of our colleagues have already promised us *résumés* on the following subjects: Recapitulation of Decisions of Previous Congresses; Electrical Units; Photometry; On the Coupling of Alternators; Electric Lamps; Methods of Taking Currents for Supplying Tramways; On Commutating Machines and Rectifiers; On the Employment of Condensers; On Non-Synchronous Generators and on the Compounding of Alternators; Electro-Deposition; On the Furnaces employed in the Production of Carbide of Calcium; Telegraphy without Wires. We shall distribute in a few days a more detailed programme of the Congress, giving, so far as they have come in, all the questions which would lend themselves to such communications, but this programme will not be exclusive. It would be interesting if we might, at the same time, along with the foregoing reports, print and distribute to the members of the Congress before the sessions, other reports prepared by English electricians on subjects chosen by them. These reports might be very short, from 8 to 12 pages, for instance, and we should have great pleasure in receiving them. We would undertake the translation and printing of them, and sending proofs to the authors. You might, perhaps, raise this question before the Institution of Electrical Engineers, and possibly recruit for us some contributors, each one of whom would treat a subject within his competence, and we reckon on receiving something, for example, from yourself." The Council had decided, Dr. Thompson said, to ask all members who respond to this invitation to submit their papers beforehand to the committee of the Council which was appointed some time ago for dealing with matters in connection with the Paris Congress.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

(To-day) FRIDAY, May 25th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House, W. Agenda: (1) Experiments illustrating the Aberration called Coma," by Prof. S. P. Thompson, F.R.S.; (2) "Notes on the Measurement of some Standard Resistances," by R. T. Glazebrook, F.R.S.; (3) "On the Strength of Ductile Materials under Combined Stresses," by J. J. Guest.

MONDAY, May 28th.

SOCIETY OF ARTS.

4.30 p.m. Meeting of the Foreign and Colonial Section, when a Paper on "Imperial Telegraphic Communication," will be read by Sir Edward Sassoon.

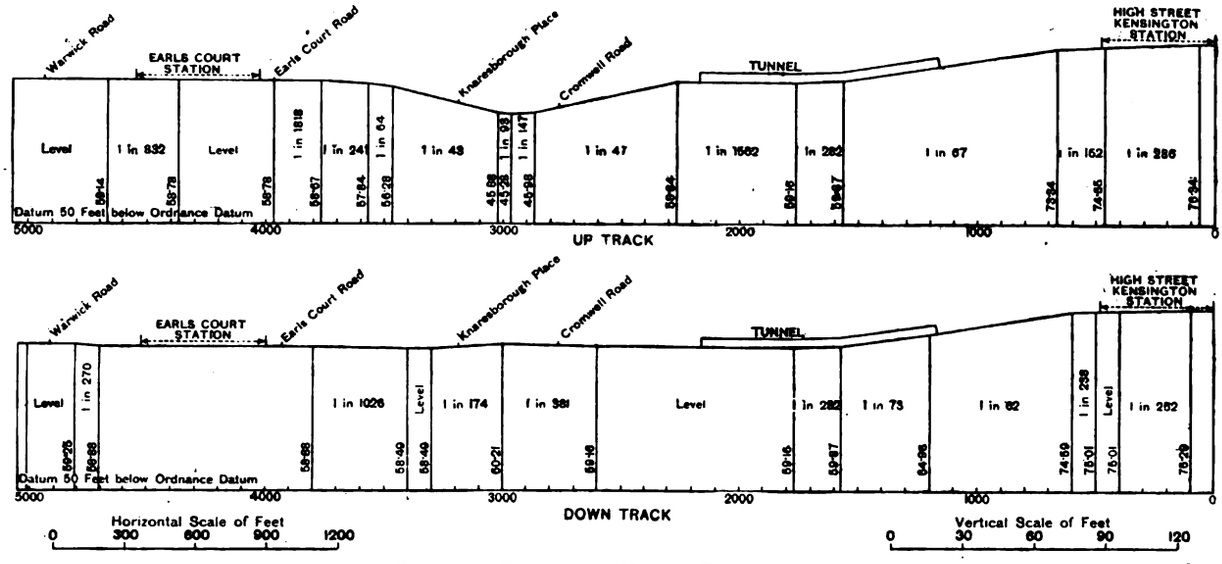
FRIDAY, June 1st. ROYAL INSTITUTION.

9 p.m. Evening Discourse by Sir Henry Roscoe, F.R.S., subject "Bunsen."

Digitized by Google

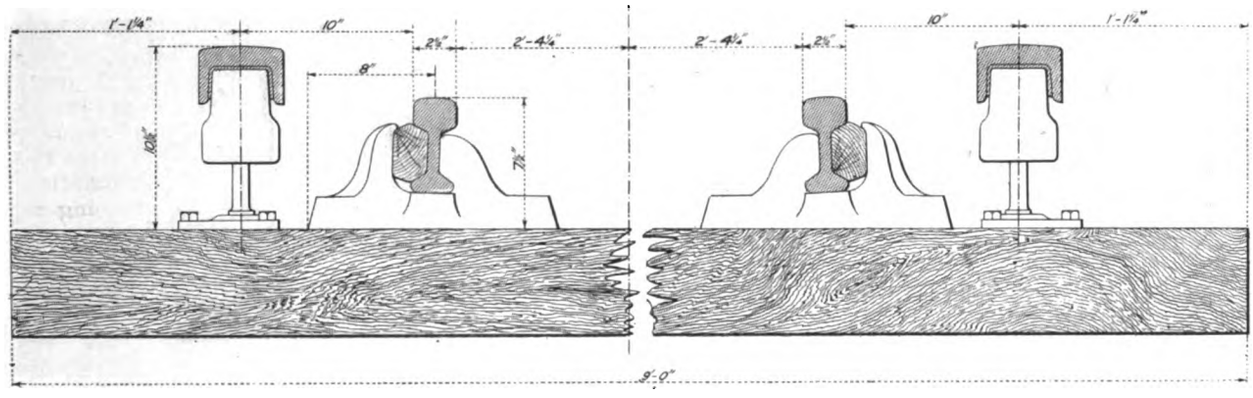
ELECTRIC TRACTION ON THE METROPOLITAN-DISTRICT RAILWAY.

On Monday last, the 21st inst., electric traction was for the first time used in working the public service on a short length of the Metropolitan-District Railway system. On that date the electric train designed by Sir John Wolfe Barry and Sir W. H. Preece was first put into operation on the regular time bill, although for some time past it has been working experimentally when the ordinary trains have not been running. An important stage, therefore, has been reached in the slow but inevitable conversion of the Inner Circle system of railways to electric traction. We deal with the historical and critical side of this development in our leading article this week. It will suffice, therefore, to give here a description of what has been actually accomplished on this experimental line. We may, however, state that in February, 1899, the sum of £20,000 was voted by the associated Metropolitan and District Railway Companies for this so-called experiment. The portion of the railway system selected for this experiment is about 5,000ft. in length, and is situated between Earl's Court and High-street, Kensington stations. It is composed throughout of double track with crossings, and a short length of side track upon which the train is shunted when not in use. Only a small portion of the route is in tunnel. The gradients of this route, as will be seen by reference to our gradients diagram, are in some places very severe, so that the section of line selected is well adapted to experimenting with electric traction on the class of train used on this railway.

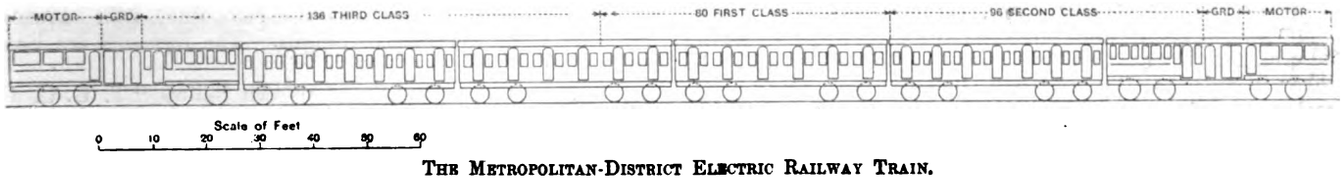


GRADIENTS DIAGRAM OF UP AND DOWN TRACKS.

This short electric line has so often been called "experimental" that some explanation of the use of this term in this connection is necessary. It required, of course, no experiment to prove that electricity was capable of running satisfactorily and safely trains similar to those on the underground railway and on quite as rapid and frequent a service. It was unnecessary to spend £20,000 to prove this. But the boards of the associated railway companies needed tangible proof that their railway system could be converted from steam to electric traction without the least interference, during the process, of their ordinary steam railway service. The engineers, Sir John Wolfe Barry and Sir W. H. Preece, were required to equip this line electrically without any interference with the permanent way, without any interference with the running of the ordinary train service, and without allowing



TRANSVERSE SECTION OF FOUR-RAIL TRACK.



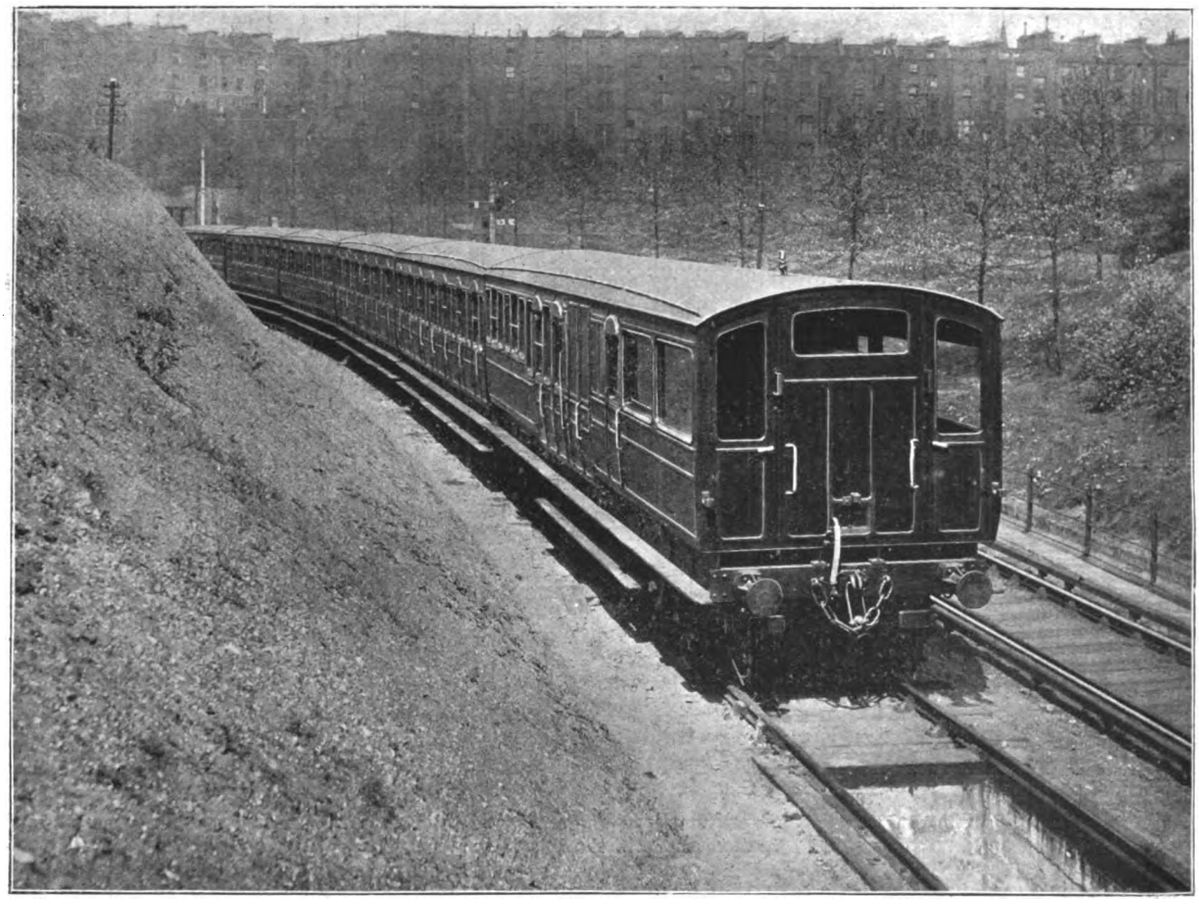
THE METROPOLITAN-DISTRICT ELECTRIC RAILWAY TRAIN.

Digitized by Google

any electric current to pass through the permanent way or the subsoil lest such should interfere with the signalling arrangements of the line. In accordance with these stringent regulations, it became necessary to adopt an insulated system throughout, and to do the whole of the construction work in the few midnight hours when the trains were not running. The contract for the electrical equipment of the power station, line and train was placed in the hands of Messrs. Siemens Bros. and Co., and it was also arranged with them that they should work the entire electrical system for six months, with a further provision that they should carry on the work for a longer period in the event of the associated railway companies so deciding. The system may be termed a four-rail system. It includes the two ordinary track rails, which are not used for any electrical purpose whatever, and two electrical rail conductors placed on either side outside the track. These electrical conductors consist of inverted channel steel weighing 75lb. per yard, and are carried on double-petticoat porcelain insulators mounted on steel bolts. One of our illustrations shows a section of the track and indicates the relative position of the electrical rails and the ordinary track rails. Two of our photographic views also show the general appearance of the electric track, viz., at the Earl's Court station and at the western entrance to the tunnel. At points and crossings the continuity of the electrical rails had to be broken in order to allow of the working of the points or the passing of trains through the crossings. The gap, however, is in no case so wide that contact is not made in front of the train before it is broken in the rear, so that the train is always in contact with the conductor rails. The channel steel forming these rails is bonded by means of stout copper strip bonds, hydraulically riveted to the steel. These bonds carry all the current, an expansion gap being provided between the rail ends.

The system of conductor rails is fed from the temporary power station by means of eight short cables. This power house is situated about 250 yards west of Earl's Court station, and consists of an iron shed which has been erected near the track. From this power house there have been carried two positive and two negative feeders, each consisting of two cables in parallel. These are connected to the near end of the conductor rail system. Each of these cables has a copper section of 0·5 sq. in. and is lead covered and armoured. Thus there are provided a forward and a return copper section of 1 sq. in. to each track. The total length of this cable is 1,000 yards. The cross-over and interconnecting cables, where the conductor rails are broken at the crossings, &c., have the same section and are lead covered, but they are not armoured in the usual way. These cable are specially protected by iron plates or by being laid in conduits.

The power house is of an essentially temporary character. It is equipped with two direct-coupled Belliss-Siemens generators and two Babcock-Willcox boilers. The boilers work at 160lb. pressure, and each is capable of evaporating at the rate of 9,000lb. per hour for short intervals. It should be explained that as there is only one train running, and this only for about three minutes out of every 20 minutes or so, the boilers are called upon to generate steam only for a few minutes at rather long intervals. The boiler furnaces are fitted with forced draught, as the temporary iron chimney would provide insufficient draught. The furnaces are hand fired.

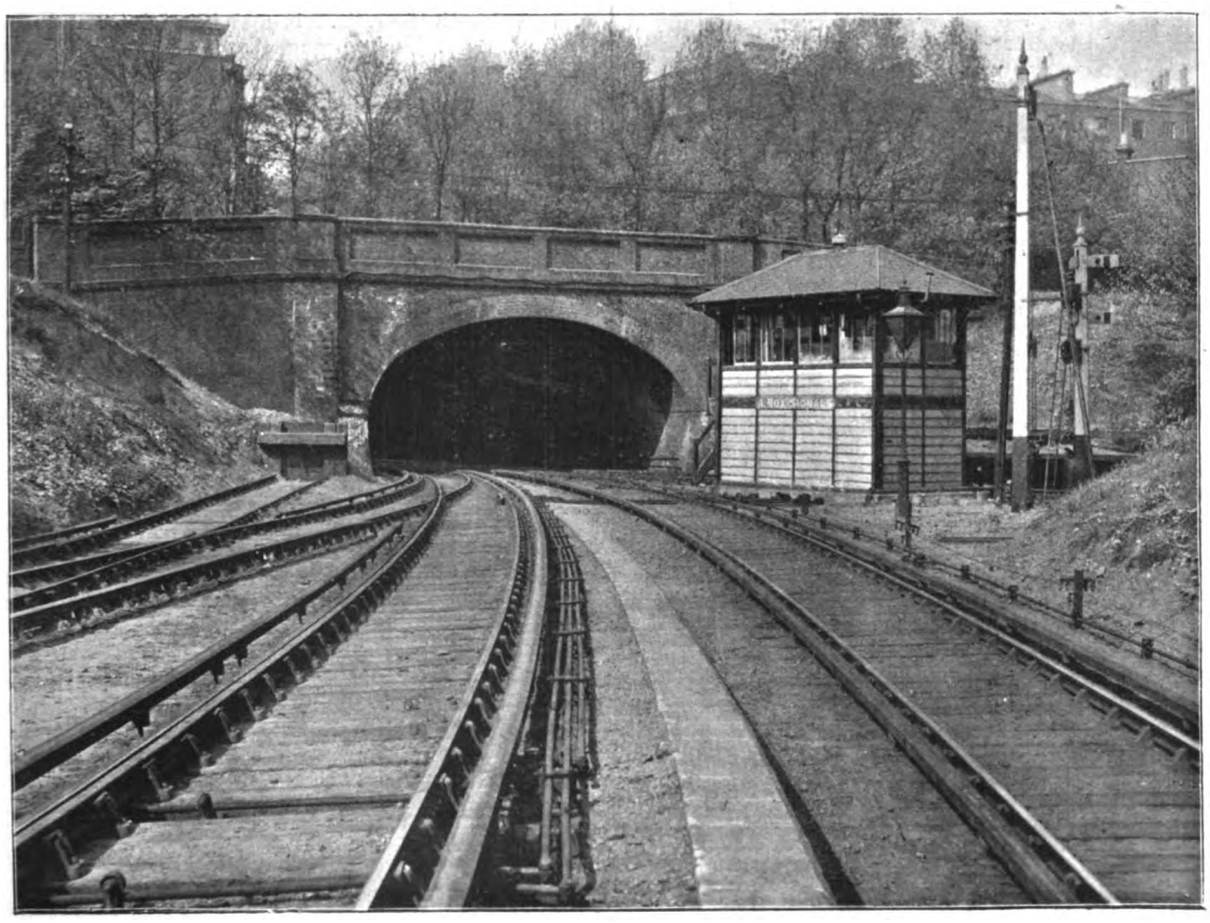


Electric Train for the Metropolitan-District Railway.

The generating sets consist of two Belliss "T. E. C. 4" engines direct coupled to two "H. B. 27 × 40" Siemens two-pole drum-wound railway generators. Each engine is capable of developing 360 I.H.P. overload, but is rated at 300 I.H.P. normal, running condensing. An ejector condenser is provided in order to get rid of the steam which otherwise might prove a nuisance to neighbours. The generators are similar in type and size to those supplied by Messrs. Siemens Bros. and Co. for the Waterloo and City Railway. They are compound-wound two-pole machines developing 385 amperes at 550 volts. The sets run at 380 revs. per min.

Digitized by Google

ELECTRIC TRACKS AT EARL'S COURT STATION.

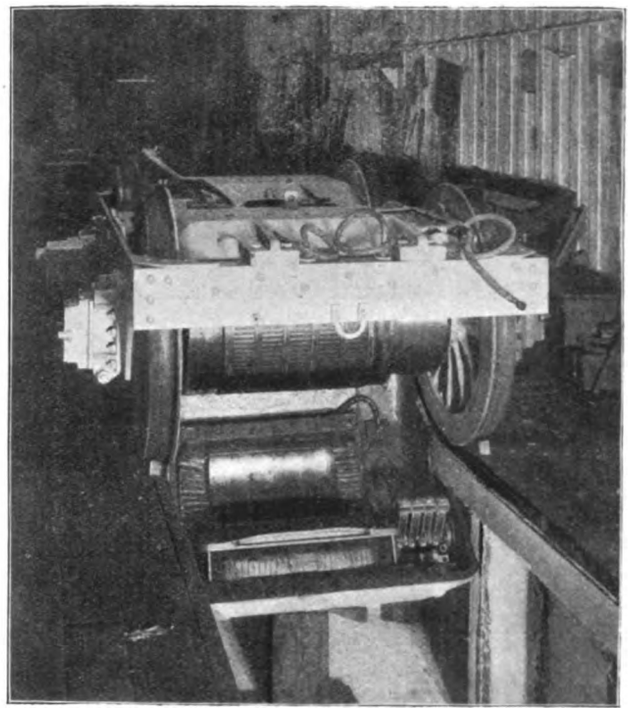


ELECTRIC TRACKS AT WESTERN ENTRANCE TO TUNNEL.

Digitized by Google

The switching arrangements at the power house are very simple in character, the chief items of interest being the large automatic cut-outs. There are four of these cut-outs, two for the feeders and one on each positive pole of the dynamos. The negative poles of the dynamos carry fuses. The feeder cut-outs are for the forward and return circuits.

A special type of train has been designed for this line, the design being such as to adapt it specially to the experimental conditions. There is no separate locomotive, the train being worked in block, and a motor carriage being placed at either end. Only one motor carriage, however, is used at a time—viz., that one in the front in the direction in which the train is moving. This arrangement, while duplicating the amount of electric motor plant, is convenient, as it obviates shunting the motor carriage. In the event of this type of train being adopted for the Inner Circle Railway, it would be necessary, of course, to have only one motor carriage as the trains on this line move in one direction continuously. The electric train consists of two motor carriages and four intermediate carriages, each being on two four-wheel bogeys. The carrying capacity of the train, as indicated in one of our illustrations, is 812 passengers, consisting of 80 first class, 96 second class, and 186 third class. The extremities of the trains consist of



Motor Truck showing Motor opened for Inspection.

the driver's cabins. Each motor carriage is equipped with four motors—viz., one on each axle of the two bogeys. The motors are of the four-pole "26 × 25" Siemens type, with the armatures built on to the axles of the driving wheels. Each motor develops a normal drawbar pull of 4,000lb. and a normal power of 110 B.H.P., the maximum power being 200 B.H.P. The motors are, of course, series wound. Within the driver's cabin, which is a spacious and entirely enclosed apartment with plenty of window look-out, the controller and other regulating arrangements are placed. The controller stands in the centre of the forepart of the cabin, and is a rather bulky contrivance, the handle resembling the steering wheel of a small yacht. It provides for 12 arrangements of the motors, as follows:

1, 2 and 3. All motors in series, and resistance in series.
4. All motors in series, without resistance.
5, 6 and 7. Two series of two motors in parallel, with resistance in series.
8. Two series of two motors in parallel, without resistance.
9, 10 and 11. All motors in parallel, with resistance in series.
12. All motors in parallel, without resistance.

Notches 4, 8 and 12 are, of course, the ordinary running notches, the others being intermediate notches for gradually getting up speed. There are no short circuit notches on the controller as it is not intended to use the motors for braking purposes. It is possible, however, to reverse the motors, while the train is running, by first bringing the controller to the zero point and then throwing over the interlocked reversing handle, afterwards throwing the motors against the train This arrangement, however, is not intended to be used in general practice, all the braking being done by means of a powerful "Standard" air brake. The air is pumped into the reservoir of this brake by means of a small electric motor and three-throw pump in the driver's cabin. The compressed air is also used to work the whistles of the train and the sanding gear. It should be observed that, in order that, the working of the trains may be carefully observed under test, an unusually large number of instruments have been erected in each cabin. Besides the main ammeter and main voltmeter, there is a separate ammeter on each motor. There is also an electric tachometer in each cabin. It is expected that the maximum current required in starting the train will be about 1,400 amperes, but the train is capable of taking a very much larger current without risk of injury. The total weight of the train, loaded, is 182 tons—viz., 72 tons for the four coaches empty, 90 tons for the two motor coaches empty, and 20 tons for the passengers.

Current is collected from the positive working conductors and returned to the negative working conductors by means of flexible cast-iron shoes suspended from the bogeys. There are 14 of these shoes on the train, seven on each side. All the positive shoes are interconnected and similarly all the negative. Each shoe is carefully insulated from the train or bogey truck by means of insulated suspension bolts. Each shoe is capable of a certain amount of vertical movement, also a very small amount of rocking movement, and the collecting surface is held against the working rail by means of spiral springs. The working conductors, we should add, are tapered at the gaps in order to provide for easy gliding of the shoe on to the conductor as these gaps are passed. As before mentioned, none of the gaps are of such a length that the train is ever in a position without a positive and negative shoe in contact with the rails. It may be of interest to add that the train is lighted throughout by means of glow lamps arranged in multiple series across the working conductors. Although no storage cells are used for this lighting, and notwithstanding that there is but one feeding point on the railway system, the lamps are but slightly affected by the starting and stopping, &c., of the train.

The Board of Trade inspection of this experimental line took place on April 3rd last, but some little delay has been occasioned on account of alterations in the signalling on this section of the line, these alterations being, however, in no way connected with the electric traction equipment. For some time past the train has been running during hours when the ordinary service of trains was suspended, and throughout last week the train was running frequently every day. On Monday last, as already stated, it was placed on the ordinary time schedule of the passenger service.

It is intended to carry out a serious of careful experiments on electric traction by means of this train, and for this purpose we understand a dynamometer car will sometimes be attached. Already certain experiments have been made. In his evidence before the Select Committee of the House of Commons considering the Manchester-Liverpool Express Railway, Sir William Preece recently stated that the train, fully loaded, had started on the very difficult gradient of 1 in 43—shown in our gradients diagram—a feat which an ordinary steam locomotive was unable to perform when hauling a similar load. Moreover, in a tug-of-war between the electric train and a steam locomotive, the electric train readily overcame the steam engine.

Our thanks are extended to Sir John Wolfe Barry and Sir William Preece for permission to publish this description of their novel electric railway and to take the photographs from which some of our illustrations were prepared. We are also indebted to Messrs. Siemens Bros. and Co. for much of the technical information contained in this article.

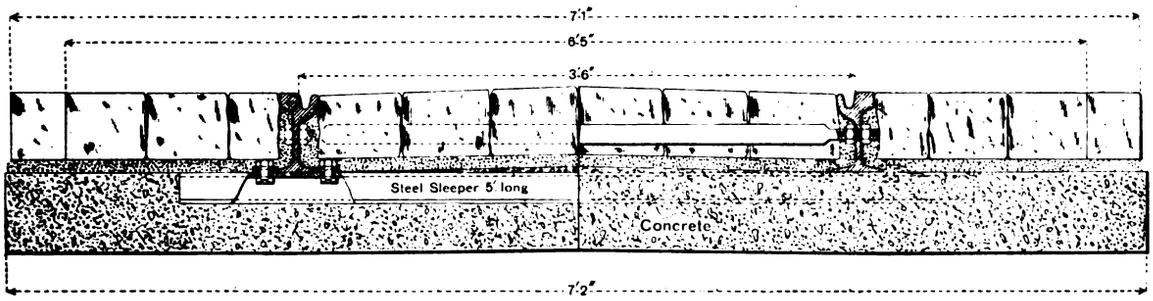
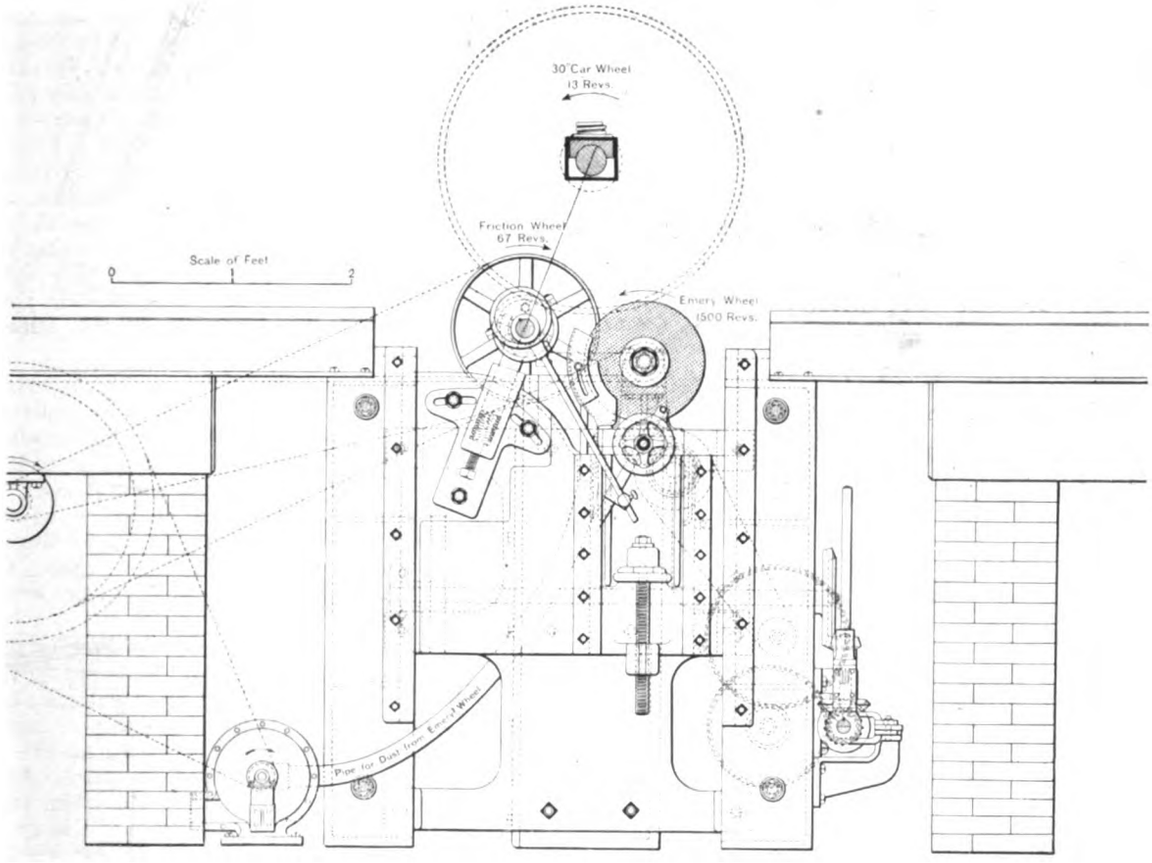
NORWICH ELECTRIC TRAMWAYS.

(*Concluded from page 127.*)

Power Station.—The power station is a substantial brick building situated near the centre of the tramway system, adjoining the river, and separated by only a narrow road from the site of the power house of the Norwich Electricity Co. Plans of the power station appeared in our issue last week. In the boiler house there are four Babcock-Wilcox boilers, each rated at 300 nominal horse-power. Each has a heating surface of 3,240 sq. ft., and works at a pressure of 160lb. The battery of boilers is fitted with Bennis mechanical stokers and a conveyer, and in the flues over the boiler a Green's economiser has been placed. The steam and other piping is in duplicate, a vertical main steam ring supplying steam to the engines and auxiliary plant. Within the spacious machinery room there is floor space for five railway generating sets, of which four only have at present been erected. These consist of Browett-Lindley tandem compound engines direct-coupled to Westinghouse railway generators. Each engine is rated at 320 H.P., and runs at 200 revs. per min. when working at 150lb. steam pressure, exhausting into the condenser. The cylinders are 16in. and 26in. diameter, and the stroke is 17in. The maximum horse-power each engine is capable of giving is 500 H.P. The flywheel carries a shaft governor of the Begtrup type, this controlling the piston valve of the high-pressure cylinder. The dynamos are of the Westinghouse multipolar railway type, each capable of developing 200 kw. at 550 volts. The machines are over-compounded for feeder drop. In addition to the railway generators, there is also a lighting set, consisting of a Westinghouse vertical steam engine direct-coupled to a 15 kw. Westinghouse dynamo, this set being used for lighting the works. The switchboard is of the usual Westinghouse railway panel type. It includes 10 continuous-current panels, one Board of Trade panel, and one lighting panel, with two spare panels.



TRANSVERSE SECTION ON TRACK.



ELECTRICALLY-DRIVEN WHEEL GRINDER.

Track Equipment.—The track is laid on a 3ft. 6in. gauge, and is of 65½lb. girder rail. The construction of the track is shown in an accompanying section. The rails are of 45ft. lengths, and are continuously cast-welded by the Falk process. As already stated, many parts of the track consist of difficult curves and gradients. Some examples of these are shown in four of our illustrations, the index numbers giving the positions of these examples of special work on the map we published

Digitized by Google

last week. Owing to the numerous gradients and curves it is expected that an unusually large number of flats will occur on the car wheels, and ample provision to remedy this has been provided for in the shape of an electrical wheel grinder, which has been erected in one of the car pits in the repairing shop at the car sheds. We give a scale drawing of this interesting machine. It consists principally of an electric motor driving an emery wheel at a rapid rate, together with a pair of friction wheels driving the car wheel at a slower rate. The wheel from which the friction wheels are run also drive a small centrifugal fan for collecting the dust from the emery wheel.

Cars.—The car equipment consists of 40 motor cars and 10 trailers, all of the double-deck type. The motor cars are equipped with Westinghouse motors and controllers carried on "Standard" Peckham trucks. An interesting feature of the car equipment is the Winslow trolley standard, a vertical section of which is shown in an accompanying drawing. The rotating head of this standard is carried on ball bearings at the top and bottom, as shown, and the tension springs are contained within the shaft. This standard gives a compact and efficient support for the trolley arm and provides for that degree of flexibility or side movement which is necessary for quick running on a trolley system in which the trolley wires are not exactly centred. It should be mentioned that the trolley head itself is not capable of moving on a vertical axis, as are many types of trolley head.

duce the scale drawings accompanying this article, and also to Mr. Bannister for kindly showing us the power house and tramway system and placing at our disposal the information contained in this article.

LEGAL INTELLIGENCE.

Castner-Kellner Co. (Ltd.) v. Commercial Development Corporation (Ltd.).

The hearing of this appeal was commenced on Tuesday last week, and the case for the appellants, which was concluded on the following Thursday, was reported in our last issue.

Mr. TERRELL, Q.C., then addressed the House on behalf of the respondents. He dealt first with the smallness of the area of the invention which was said to be infringed, pointing out that he had pressed witnesses to say what it was that was said to be done by the Kellner patent which had not been done by other and previous patents. The most that any of them could say for it was that by its use a smaller quantity of mercury was required for the operation. There were three questions for their lordships' decision, which he submitted to the House in this way. The first was this: The respondents contended that the principle introduced in the final specification of the Kellner patent was not merely a departure from the provisional specification, but was absolutely a contradiction of it. Secondly, for that very reason, if the appellants were right in saying that the modification was not a contradiction of what was contained in their provisional, the respondents had not infringed the appellants' patent; thirdly, the respondents said that the appellants had failed to show that there was any subject-matter for this invention by their evidence according to the requirements of patent law. It was not enough to secure a patent, that an invention was claimed for a useful machine, if the invention was not capable of doing something that in itself was useful. He then described at some length Kellner's invention, and contrasted it with the Jensen, Sinding-Larsen, and other patents that had preceded it, and finally described in detail the apparatus of Rhodin, which consisted of a set of cells containing a solution of salt, in which were carbon electrodes. These cells, he explained, dipped into a circular pan of mercury, which acted as a cathode, filling up the intervals between the cells containing salt over which water was placed, and passing an electric current over the salt solution. Sodium was deposited on the mercury cathode forming an amalgam with the mercury, and as the cells were given continuous rotation, the amalgam so formed was brought into contact with the over-lying water and formed caustic soda by the action of the water and sodium. To ensure circulation of the mercury ribs were placed on the bottom of the pan causing the mercury to flow outwardly along its surface. It would thus be seen that the elements of Rhodin's apparatus consisted of a stationary vessel containing a layer of mercury, lying in the bottom whereof were a series of bells with their lower edges just dipping into the mercury containing the salt solution to be decomposed. The object of the ribs at the bottom of the vessel were, to arrest the flow of the mercury, and to make it flow relatively to the bells, whereas, if it were not for the ribs this result could not be obtained. Contrasting the respective specifications of Rhodin and Kellner, he maintained that, if the respondents infringed the latter, it was because there was disconformity in the appellants' specifications, and if there was no disconformity then the respondents did not infringe.

A model of Rhodin's apparatus was at this stage of the argument brought into the House and placed on the table before the Lord Chancellor. Mercury was poured into it by a gentleman representing the respondents' company, who proceeded to explain how the apparatus worked.

The LORD CHANCELLOR: When I turn the handle at the authorised speed of four turns to the minute, do I, in fact, turn the mercury in the vessel, or is it only an optical delusion?

Mr. TERRELL: The handle, in fact, turns the mercury about. That can be shown by placing on the surface of the mercury a scrap of paper. The machine in use would be some 4ft. in diameter, and turning its handle four times in the minute would produce the same amount of movement in the mercury as turning the handle of the model at the speed of 20 revolutions a minute. Resuming his argument, the learned counsel proceeded to deal with the distinctive features of the Rhodin process and to argue the question that it contained the subject matter for an invention. Subject matter of a patent, he said, involved utility.

The LORD CHANCELLOR: This word "utility" does not appear in the statute, and in no decision of the courts has the word been interpreted in the sense in which learned counsel used it. Of course a mere idea, which is incapable of being applied to any practicable use, cannot be the proper subject matter for a patent.

Mr. TERRELL agreed that in every valid patent there must be the element of "invention." There must be the exercise of an inventive faculty, and the invention must do something. It must accomplish some purpose. In this case the appellants to succeed must show that their patent accomplished something, and they could not show that it accomplished anything which the original method of using mercury did not equally well perform. He maintained that, reading Rhodin's specification and taking it, as he was entitled to do, as a description of what the respondents proposed to do, there was no evidence that the respondents using Rhodin's process must of necessity infringe the appellants' patent. He pointed out that the appellants had never worked Kellner's patent, and he went so far as to assert that it could not be worked

Digitized by Google

because the Kellner apparatus in fact would not effect the objects or produce the results claimed—in short, that the patent was both worthless and void for want of utility. The appellants had been the owners of Kellner's patent since October, 1895, yet they had never attempted to work commercially or to lay down any plant or apparatus made in accordance with the specification, but had carried on business by means of an apparatus on Castner's principle. The apparatus the respondent's proposed to use had not been shown by the appellants to be in accordance with any apparatus or invention claimed in Kellner's specification, and therefore this appeal on the ground of an alleged infringement must fail.

In conclusion, he submitted that the appellants had failed to show that the decision of the majority of the Court of Appeal was erroneous.

Mr. ASTBURY, Q.C., followed: There were three grounds upon which he should submit that this appeal should be dismissed, and the judgment of the Court of Appeal affirmed. Briefly they were these: (1) Because the appellants' complete specification described, and in claim 3 claimed, an invention different from and larger than that described in the provisional specification. The patent sued on was also void (2) for want of subject matter, and (3) because of prior publications. At the trial various diagrams and models, including a working model of a machine constructed according to the specification of Rhodin's patent (No. 21,509 of 1896) and machines constructed according to the specifications relied upon as prior publications, were put in evidence. These showed that prior to the appellants' alleged patent the use of mercury as a cathode in electrolysis, and to form a seal between the cells of electrolytic apparatus, and the process of the electrolysis of alkaline salts with the aid of a mercury cathode were well known; and prior inventors had pointed out the difficulties and the means by which those difficulties could be surmounted. All that was left open, therefore, for any inventor dealing with this process was to devise a particular or suitable apparatus by which the desired object could be successfully secured. Carl Kellner, in his provisional specification, said that it had reference to an apparatus for the electrolysis of alkaline salts with the aid of a stationary mercury cathode, in which the amalgam formed by electrolytic action had its location changed from the decomposing chamber in which it was produced to a combining chamber in which it was decomposed, and the cation combined with water, an acid or other body by the shifting of a partition, which was adapted to be moved to and fro in the mercury, and served to separate the two chambers from one another. This portion was made in the form of a bell, closed at its lower edge by a mercurial seal, and enclosing the decomposing chamber, so that the amalgam formed in the latter was caused by the shifting of the bell to have its location alternately on one side and on the other side of the bell, without itself changing or moving its position, and thus got into the combining chamber, while the mercury on the other side of the partition, which was previously situated in the combining chamber, effected the amalgamation of the metal that was being separated by the eletrolytic decomposition of the electrolyte. Kellner claimed that in this way a considerable output could be obtained from the apparatus with a small quantity of mercury, but at the trial evidence was given that his alleged invention really required the use of as much or more mercury to produce a given result than Rhodin's patent, and, therefore, the claim that his apparatus produced a saving was disproved. So, too, Kellner's statement that this economy was due to his method, by which both operations could take place at one and the same time and uninterruptedly, was only the statement of a fact that had already been noted and covered by other apparatus of prior date. Then Kellner's provisional specification went on thus: "In order that the mercury shall not become displaced by the lower end of the bell sliding over the bottom of the trough B. when the bell is being moved over slots or notches e or f^2 are provided in the lower edge of the bell, as in Figs. 1 and 4, or in the bottom of the trough, as in Fig. 5," and after describing the manner of working the apparatus the specification concluded as follows: "It will thus be seen that by the to-and-fro movement of the bells the transposition of the amalgam formed in the decomposing chambers to the combining chambers, and the practically continuous formation of caustic soda in the latter are caused to take place alternately on the one side and on the other side of the anodes, whilst the mercury cathode itself remains at rest."

The LORD CHANCELLOR: Do you say, Mr. Astbury, that the essential characteristics of Kellner's invention, as shown by his provisional specification, consists in devices for keeping the mercury cathode stationary and in the to-and-fro or alternating motion of the bells, alternately charging and discharging certain patches of the mercury surface with sodium?

Mr. ASTBURY: Certainly, my Lord; that was the evidence given at the trial also by the experts we called.

The LORD CHANCELLOR: And you contend from the specification of Rhodin's patent that in his process the mercury is agitated and churned up, and made to flow continuously from the centre to the sides of the vessel containing it and back again, and that this distinguishes it from the alternating method described by Kellner in his provisional specification?

Mr. ASTBURY: Yes, my Lord. In Rhodin the continuous flow from the centre to the circumference of the vessel containing it, and back again, gives this result, that a definite percentage or richness of sodium throughout the whole body of the mercury is maintained instead of Kellner's alternating method, as described in his provisional specification, the apparent feature of which was to charge and discharge certain patches of the mercury surface, and then, as a distinct operation, to discharge the same.

The LORD CHANCELLOR: How do you say that Kellner's provisional essentially differs from his complete specification?

Mr. ASTBURY: By describing an alleged modification which, in fact, is an absolutely different method of using the apparatus.

Lord MORRIS: Do you say that Castner's patent anticipated Kellner's complete specification?

Mr. ASTBURY replied that from the specification of that patent it would appear that the electrolytic operations in such process also took place simultaneously and uninterruptedly, and that no greater quantity of mercury was used in such apparatus than in Kellner's. The alleged modification introduced by Kellner in his complete specification consisted in this: that instead of being slid along rectilineally, the bell E or the vessel A, or the bottom of the latter, might have a rotary motion imparted to it. That alleged modification was an absolute departure from the essential feature of the invention as originally described, which said nothing about the alternating process of working with a stationary cathode, and reverted to the continuous process which had been described in Castner's by agitating and stirring up the cathode and by producing and maintaining a definite state of richness in sodium throughout the same, as distinct from charging and discharging definite patches of the mercury surface.

The LORD CHANCELLOR: Whether there is any practical difference between moving a bell through mercury and moving mercury under a bell,—a question over which experts differed at the trial—you say that any process by which the mercury is intentionally moved or disturbed otherwise than to the least possible extent by moving bells of salt water over it is outside, and cannot fairly come within, Kellner's real invention.

Mr. ASTBURY said that was the view of the Court of Appeal, and, he submitted, the right view, for Kellner's alleged modification was inconsistent with the original idea. It could not be successfully contended that an invention for an apparatus for keeping the mercury still was one for an invention for an apparatus for keeping the mercury moving. Claim No. 3 covered both inventions, and was such a departure from, and such an extension of, Kellner's real invention as to render the patent invalid. The learned counsel then addressed himself to the question of infringement. Describing the process as being one to transfer the mercury from one cell to another, he referred to Mr. Grindle's evidence, which showed the distinction between the appellants' and the respondents' machine in respect that the Rhodin apparatus of the respondents had ribs at the bottom of the vessel. The learned counsel explained in detail the differences between the apparatus and the appellants' and respondents' methods of distributing the electric current. Without the ribs, the Rhodin apparatus would not work. Mr. Astbury referred to the evidence of Mr. Dugald Clerk, who said that in Kellner's arrangement there must be one cell in the path of the other—the combining cell being in the path of the decomposing cell. In the respondents' case the combining chamber was out of the path of the decomposing cells altogether. Mr. G. A. Grindle had described Rhodin's apparatus as being efficient in consequence of the perfect circulation of the mercury, and said that Kellner's apparatus was not practical, and he had never heard of anybody working it. The appellants' patent was of a very limited character and very inefficient operation. It was only an apparatus for carrying out a perfectly familiar process. If there was any invention which could be patented it lay in the difference between the Kellner and the Castner specifications. In summing up, counsel said that Lord Justice Rigby was right in holding that there was no subject matter for the appellants' patent. With regard to disconformity Figs. 7 and 8 differed from Fig. 1, and went back to a former model, and the authorities showed in such a case that there was disconformity. Turning to the last question for decision, namely, that of infringement, the learned counsel said the plaintiffs, to succeed, had to show that their invention was a stationary cathode. If, in fact, there was any disconformity between Kellner's provisional and his complete specification, then Kellner had not invented a stationary cathode, and Kellner's patent was anticipated. Rhodin's apparatus did not infringe the plaintiffs' invention for several reasons. The defendants' apparatus made on Rhodin's specification had no stationary cathode, and there was no intermittent movement or its equivalent. Rhodin's apparatus discharged mercury in bulk and did not discharge in alternate patches; moreover, there was no water space between the mercury and the bells. Again, in Rhodin's there were no equally-sized charging and discharging cells following each other and together carrying the whole cathode; then the defendants' patent had a very much larger annulus—eight or nine times as large as Kellner's—which gave the opportunity of using a greatly increased current. Again, in the Rhodin patent the surface of the mercury outside the bells was revolving, and the radial ribs prevented it revolving underneath the pot and threw it outwards towards the periphery. This outward flow of mercury together with the large outside annulus were the superior points of Rhodin over Kellner. Indeed, if the mercury revolved underneath the pot itself, the whole thing would be a poor inefficient apparatus, very much the same as the Kellner one. In Kellner's provisional specification the whole thing consisted in moving the bells from a definite patch of mercury charged with sodium to a definite uncharged patch, the charged patch then coming into contact with water. But in his complete specification, in Figs. 7 and 8, Kellner was dealing with definite patches. Therefore the defendants contended that his Figs. 7 and 8 were inconsistent with a stationary mercury cathode, for the edge of the partition dividing the two chambers really acted as a stirrer. There was as much stirring in Kellner's Fig. 7 as there was in Castner's. To produce the flow of mercury by friction of the bottom of the containing vessel was the same thing as producing the flow by means of a paddle. The learned counsel again referred to the evidence given by the defendants' witnesses at the trial—especially that given by Mr. Dugald Clerk and Mr. G. A. Grindle—and submitted that the invention of Rhodin differed in every important detail from that of Kellner, and he was about to cite authorities in support of his contention, when—

The LORD CHANCELLOR said there was no principle of law in dispute between the parties. It was a dispute as to facts, and therefore authorities were quite unnecessary.

This closed the defendants' case.

Digitized by Google

Mr. FLETCHER MOULTON, in reply, addressed himself principally to the question of infringement. He claimed that the plaintiffs held the patent by which for the first time in a satisfactory way an apparatus for the electrolysis of alkaline salts with the aid of a stationary mercury cathode were produced, and he proceeded to show how the Kellner patent increased the usefulness and differed from the invention of Castner. Having explained at length the essentials of the two patents, he showed in what respects he considered that Rhodin's patent infringed, and then went at great length into each point of difference in the Rhodin and Kellner patents which Mr. Astbury had advanced. He submitted that the nature of the invention described in Kellner's specification must be considered in the light of the evidence given at the trial, and with that view he went into the evidence of Lord Kelvin and Mr. Swinburne, the plaintiffs' chief witnesses. He traversed Mr. Dugald Clerk's evidence to the effect that if the mercury were moved from one chamber to another it did not matter whether or not it moved in relation to the vessel which contained it. In Rhodin's there was a large annulus outside the bells in which most of the combining action went on. The ribs at the bottom tended to make the amalgam flow outwards of this annulus. Mr. Astbury had said it was impossible in Rhodin's to have alternate patches covered and uncovered; there was a constant stirring and not a stationary cathode. The mercury in Rhodin's apparatus was purposely kept at a high state of churning or agitation. These and other points Mr. Astbury asserted distinguished Rhodin's from that of the plaintiffs'. He (Mr. Moulton) submitted that the evidence of the plaintiffs' witnesses showed that was not the case. Lord Kelvin, in his evidence, said the advantage of Kellner's method was that there were no helical blades. Stirring was not wanted; in fact, the less the mercury was stirred the better. In Kellner's the mercury moved in relation to the fixed cells; the electrolyte and the water were included in the cells; they were stationary, whereas in Rhodin's the cells were moved in relation to the mercury, but in both of them Mr. Swinburne said there was just that agitation which would be caused by the edges of the cells dipping into the mercury. In conclusion, he submitted that none of the reasons Mr. Astbury had given why the delendants' invention did not infringe were well founded, and he invited the House to say that the claim for infringement had been proved, and that the plaintiffs were entitled to judgment.

This concluded the case, on Tuesday, and the Lord Chancellor announced that the House would take time to consider its judgment.

Legal Intelligence continued on p. 184.

ELECTRICITY WORKS ACCOUNTS.

Liverpool Corporation Tramways.

In our table subjoined we have attempted to summarise the more interesting figures of the working during 1899 of the extensive tramway system of Liverpool. The official report does not entirely separate the accounts of the electrical section from those of the horse-worked sections — such a separation is hardly possible. The working expenses are, however, separately available, and a comparison, even to this limited extent, between the two systems of working is, we think, possible and of course most interesting. In our analysis the small proportion of the "Road and Traffic Expenses," and of the "Horse-keeping and Maintenance" charges, which are chargeable to the working expenses of the electrical system, have been so charged; and, so far as we can see, the total working expenses (though, of course, not the elements which contribute to them, although of the same denomination), as set forth in our table, are directly comparable.

It will be seen that not only is the revenue per car mile on the electrical system higher than on the horse section, but that the working expenses on the electrical section are no more than about 6·0d. per car mile, as compared with 9·5d. on the horse-worked sections. These results are significantly similar in their indications to those we were able last year to record for Glasgow, and in both cases the figures in our analyses are eloquent of the unqualified success which has attended the introduction of electric traction in these towns.

The Brighton and Rottingdean Seashore Electric Tramroad Co.

In our remarks on the 1898 accounts of this interesting little line, we stated that it was expected that as a result of the purchase of power from the Corporation, and the reduction in the tariff for its supply, the "locomotive power" item in the accounts would be so reduced as to enable the concern to show improved financial results. Unfortunately, while a

very decided reduction in the costs per train mile has taken place in the working during last year—especially during the latter half—the receipts per train mile have dwindled very materially owing to the decrease in the passenger traffic. This falling off in the number of passengers carried during the year amounted to about 11 per cent., and is significantly shown by a comparison of the receipts per train mile during the latter halves or the best portion of the two years. It will be seen that the total has dropped from 13·2s. in 1898 to 8·5s. in 1899, or 36 per cent. On the other hand—and this is a most hopeful sign—the costs in the same periods show a diminution of nearly 46 per cent., while the ratio of the expenditure to revenue fell from 70·3 to 59·6 per cent.

The following is a list of electric railway and tramway works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

Blackpool & Fleetwood (Co.)	Mar. 30, 1900	Glasgow Corporation (Mun.)	Aug. 11, 1899
Brighton & Rottingdean Seashore (Co.)	April 7, 1899	Isle of Man (Co.)	May 27, 1898
Bristol Tram & Carriage (Co.)	Feb. 17, ,,	Leeds City (Mun.)	June 2, 1899
Br'mpt'n & Pico'dilly Cir. (Co.)	July 8, 1898	Liverpool Overhead (Co.)	Mar. 30, 1900
City & South London (Co.)	Mar. 30, 1900	New General Traction (Co.)	May 27, 1898
Douglas Southern (Co.)	May 27, 1898	Oldham, Ashton & Hyde (Co.)	Mar. 30, 1900
		Waterloo & City (Co.)	Feb. 17, 1899

BRIGHTON & ROTTINGDEAN SEASHORE ELECTRIC TRAMROAD.

Worked by	Brighton and Rottingdean Seashore Electric Tramroad Co.
Date of Commencement of Working	November, 1896.
System	Overhead trolley at 550 volts.
Chief Engineer	Magnus Volk.

Half-year ended	June 30, 1898.	June 30, 1899.	December 31, 1898.	December 31, 1899.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON

Telephone: 949 Holborn. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to THE EDITOR.

All letters for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of THE ELECTRICIAN" *Printing and Publishing Company, Limited. The well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. ELTON YOUNG, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. FISHER and J. C. H. DARBY. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. PHILLIPS. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. FISHER. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. RAPHAEL. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof J. A. EWING, M.A. New edition. Price 10s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. AYRTON. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DANE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICE.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (950 pages), bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

ELECTRIC TRACTION ON THE "UNDERGROUND" RAILWAY.

Monday, May 21, 1900, is a date to set down in the annals of electric traction, for on that day an electric train was first put on the public passenger service on the Metropolitan-District Railway. The event, important though it undoubtedly must be in any circumstances, was, however, deprived of some of its glamour, owing to the fact that London is already familiar with electric traction on underground railways. The opportunity has been missed by the directorial Boards of the Metropolitan and District Railway Companies of being first in the field; and, despite its significance, the event of Monday last falls flat. Everyone is asking, Why was not this thing done five or ten years ago? Instead of being an event in the vanguard of railway engineering, it is but an inevitable capitulation to the force of circumstances on the part of the two associated railway companies, who have striven to set their faces against it as long as possible. Nor can we discover, in this so-called "experiment" in electric traction, anything more than an attempt to put off the day when the entire Inner Circle system must be electrically equipped, or cease to enjoy any measure of public patronage.

It will be remembered, doubtless, by our readers that in February, 1897, a committee was appointed by the Board of Trade "to inquire into the [then] existing system of ventilation of tunnels on the Metropolitan Railway, and report whether any, and, if so, what steps could be taken to add to its efficiency in the interests of the public." This reference is more closely related to electric traction than may appear at first sight; for, in October, 1897, the Committee made its report, the sum and substance of which was that "by far the most satisfactory mode of dealing with the ventilation of the metropolitan tunnels would be by the adoption of electric traction." We gave the full text of the recommendations in our leading article of October 15, 1897 (*The Electrician*, Vol. XXXIX., p. 820); and on that occasion we observed that "in the face of such unmistakable conclusions on the part of a strong and competent departmental committee, and with the pronounced success of electric power as a means of propulsion on railways confronting it, it is to be hoped the Metropolitan Railway Co. will no longer hesitate to adopt electric traction." As regards

Digitized by Google

the actual ventilation to be adopted, we quote again the fifth and final recommendation of the Committee :—

5. Therefore, as a temporary measure, the Committee are prepared to recommend that the construction of the proposed additional openings, which would be found useful even when the line is worked electrically, should be allowed, but only upon the condition that, unless electric traction be adopted, or some satisfactory artificial ventilation be introduced within three years after the passing of the Act authorising these openings, it shall be made incumbent upon the company to close them if called upon to do so by some competent authority to be named by Parliament.

The three years have nearly expired, but what has been done to carry out these recommendations? For answer, we see only the "experimental" line between Earl's Court and High-street, Kensington—scarcely any of it in tunnel—and the bill which has been quite recently promoted by the associated companies, to obtain powers to erect a power station and work their lines electrically. Emphatically this is a policy of dawdle and delay. Of "experimental" line there was no real necessity whatever; and the bill should have been promoted as soon after the report of the Board of Trade Committee as it could be properly drafted. Note what happened instead. For nearly a year the railway companies appear to have done nothing; but in the early summer of 1898 they awoke from their lethargy to the extent of appointing two eminent engineers, a renowned bridge builder and a leading telegraph expert—to wit, Sir John Wolfe Barry and Sir William Preece—to report to them about the possibilities of electric traction. What these engineers told the directors we do not know; but they had plenty of material at hand to enable them to make out a clear case in favour of the immediate adoption of electric traction on the Inner Circle. Incredulous as the directors seem to have been at the outset, it might reasonably have been supposed that they would be convinced by the successes already achieved with heavy electric traction elsewhere. But no: not easier than other mortals can directors be convinced against their will. So they met in solemn conclave and voted £20,000 between them, for the purpose of presenting their two expert engineers with a pretty little problem, which would keep things quiet for a couple of years or so. Now, there happened to be a short length of railway over which but few trains passed daily; it lay between Earl's Court and High-street, Kensington. "Go," said the directors to their experts, "erect your electrical apparatus on that little bit of our line, without in the least disturbing our precious permanent way, or our trains, or our signals; spend £20,000 in doing this thing, and afterwards we will come and see if it will work." In spite of the stringent conditions the electrical equipment was successfully put in place; nothing in the permanent way was disturbed, not a single train was interfered with, and an insulated return conductor was provided, so that there should be no disturbance from earth currents. Then came the directors to view the "experiment"; and, doubtless to their amazement, the whole thing worked successfully—worked as any electrical engineer three years ago would have predicted it would do.

It is difficult to perceive what the associated railway companies, or anyone else for that matter, are going to learn from the experiment at Earl's Court. Doubtless the expert engineers and their friends will take advantage of the electric train to make useful measurements and tests; we hope they will do so, and that the results will be communicated to the Institution of Electrical Engineers. But it is hardly likely that the directors have voted £20,000 to enable electric traction engineers to make technical experiments for themselves. Yet the purpose of the line is by no means evident. For, the particular system and the mode of working adopted are certainly not designed to show that electric traction is cheaper than steam locomotives; the experiment is to be carried out without regard to economy of working. Neither can it be claimed that the particular type of train or system of track-work are such as the engineers would recommend for a permanent equipment of the underground railway system. Indeed, it appears to be certain already that, in the event of such extensions, quite different arrangements would be made. In the Inner Circle, for example, it would be far better to place the working conductor or conductors near to the top of the tunnel, where there would be less risk of their giving shocks to platelayers or becoming earthed by being accidentally connected to the track rails by means of, say, a crowbar. At present, the temptation to a tired platelayer to sit down on the flat top of the 500-volt working conductor, and put his feet on the track rail, may only be overcome after saddening experience. Not that we anticipate serious mishaps on this short length of scarcely-used track; the system adopted is suitable enough for the purposes of the "experiment." In fact, the directors have now had it demonstrated to them that electric traction *can* be provided on their lines on the conditions they have stipulated; and we trust that they are satisfied thereby, and that they will proceed without further delay to look at the matter in the light its seriousness demands. No more time should be lost in electrically equipping the entire Inner Circle system.

A CENTURY OF CHEMISTRY AT THE ROYAL INSTITUTION.

(*Concluded from page 136.*)

Lecture IV.

At the Royal Institution on Thursday afternoon, May 17th, Prof. J. Dewar, F.R.S., delivered the fourth and concluding lecture of this course. Resuming his remarks on Faraday's experiments on the liquefaction of gases, the lecturer pointed out that Thilorier's discovery of the manufacture of solid carbonic acid led to a resumption of Faraday's experiments, which had been temporarily suspended. He soon arrived at the conclusion that both low temperatures and considerable pressures were necessary for the liquefaction of every gas, and that there invariably existed a Cagniard-de-la-Tour state for every gas. The use of solid CO_2 by Faraday is analogous to the use of liquid air at the present time. Faraday next investigated the solubilities of some of his liquefied gases, finding that liquid CO_2 was a feeble, and liquid NH_3 a very powerful solvent. He examined also the nature and properties of india-rubber, which he proved to be a hydro-carbon, losing all traces of its elasticity when cooled to a very low temperature. After referring briefly and rapidly to the remaining chemical and electro-chemical investigations of Faraday, Prof. Dewar turned to Sir Edward Frankland, who continued the investigations of Faraday in the domain of organic chemistry, considerably extending that science by original investigations and successful speculations which made him second to none as an experimenter of the modern type. Frankland was the first to conceive the idea of "atomicity," or "valency" as we now prefer to call it, in chemical action, and one of the first also to examine the nature of flame. The principal technical work with which Frankland was notably connected was (1) the analysis of the water supplies of the metropolis and Great Britain, and (2) the enrichment of coal gas.

In conclusion, Prof. Dewar made references to two other chemists connected with the Institution. First, to Dr. Odling, who made himself principally remarkable for his clear and philosophical grasp of the whole field of chemical theory; and second, to Dr. John Hall Gladstone, whose name would be chiefly remembered by future chemists and physicists for his notable work leading to the formulation of the well-known Gladstone's law of refractive powers of solutions, and who was still amongst us, actively occupying himself in chemical investigations.

PHYSICAL SOCIETY.

At an ordinary meeting, held May 11, 1900, Prof. O. J. Lodge, F.R.S., President, in the chair, a discussion of Prof. Lodge's Paper,

"On the Controversy Concerning Volta's Contact Force,"

was commenced by Prof. Armstrong.

Prof. ARMSTRONG expressed his indebtedness to the President for stating clearly what we are trying to understand, and said that it was hardly time for chemists to enter the discussion so long as physicists themselves differed. There had apparently been a change of front since the effect was supposed to be due to (1) chemical action between metals, or (2) oxidation. Prof. Lodge's view is intermediate but approximate to the second. Prof. Armstrong said that, from a practical point of view, the existence of the effect was unknown, because sufficient precautions had never been taken to prevent chemical action. He urged the continuance of experiments similar to those carried out by Mr. Spiers, and stated that modern ideas of chemistry were favourable to the view which Prof. Lodge had taken up with regard to the Volta effect.

Mr. R. T. GLAZEBROOK made some remarks upon the meaning of the term E, which occurs in the expression for the Peltier effect at the junction of two metals. If we confine our attention to an infinitesimal cycle at the junction of two metals at slightly different temperatures, we get the equation for the Peltier effect, in which E is the potential difference at the point considered. If, then, assuming reversibility, we sum up all the infinitesimal cycles round a circuit, and get a finite cycle, the E.M.F. of the circuit is a function of the two temperatures between which it is working. Differentiating with respect to temperature the total E.M.F. of the circuit, we get an equation which applies to the circuit as a whole, and in which E is the total E.M.F. round the circuit.

Mr. PRICE asked if any critical experiment could be suggested to settle the question.

Dr. LEHFELDT called attention to some experiments which had been performed to measure the potential difference between an electrolyte and a gas. The electrolytes considered were chiefly aqueous solutions, and the potential differences observed varied largely. The surface tensions of the liquids were measured, and it was shown that the variations in the potential difference were very similar to those in surface tension. This suggests, in the case of electrolytes, true physical surface effects and not chemical action.

The CHAIRMAN remarked that Dr. Lehfeldt evidently looked upon the metal-ether boundary as being the effective one. The experimental evidence was not sufficient to say exactly which was the effective contact, but it seemed to show that the metal-ether effect was of the same order of magnitude as the oxygen-layer effect. According to Helmholtz, they ought to be related, and so they were.

The CHAIRMAN then read a Paper, by Mr. J. B. TAYLER, on

"The Heat of Formation of Alloys."

Experiments have been made upon alloys of lead with tin, bismuth, and zinc, and of zinc with tin and mercury. The method employed consisted in dissolving (1) the alloy, and (2) the corresponding mixture of metals in mercury and measuring the heat of solution in each case. On the assumption that the solutions obtained are identical, the difference between the heat of solution of the mixture and that of the alloy is the heat of formation of the latter. The calorimeter was a thin glass tube, silvered on the outside, and supported by a stouter tube, silvered on the inside. Suitable arrangements were adopted for the introduction of the metals or alloys, which were used in the form of filings. Solution was often complete in less than a minute, and rarely took more than two minutes and a half. The alloys first experimented upon contained their constituents in equivalent proportions, and the heats of formation were found to be small in comparison with those found for brass by Galt and Baker. It was thought that only a small percentage of the atoms present had entered into definite chemical combination, and that more reliable results would be obtained by dissolving a small quantity of one metal in an excess of the other, and calculating from the experimental results the heat of formation of the gramme-molecular weight of compound upon the supposition that the whole of the small quantity of metal had entered into chemical combination by the exercise of its normal valency. Using these numbers so obtained to find by Kelvin's theory the potential difference which should exist between the metals concerned when put in contact, results were arrived at which agreed neither with the Volta effect nor the Peltier effect, but which were considerably nearer the former than the latter.

A Paper on

"The Want of Uniformity in the Action of Copper-Zinc Alloys on Nitric Acid"

was read by Dr. J. H. GLADSTONE. Experiments have been made by dissolving copper-zinc alloys in nitric acid, following the method of Dr. Galt, and adopting the precautions mentioned by him. The reaction between nitric acid and these metals or alloys is very complicated, and there is a difference between the products in the case of an alloy and in the case of the equivalent mixed metals. The gases evolved being small in the experiments performed, attention was directed to the determination of the substances remaining in solution, *i.e.*, the nitrous acid and ammonia. The alloys gave much more nitrous acid and less ammonia; in fact, two of the alloys employed produced no ammonia. Discrepancies in results may be due to the fact that the zinc and copper in contact form a zinc-copper couple which in the presence of acid sets up a vigorous action, and produces a different evolution of heat. Difficulties arise in the investigation because the alloys used may not be definite chemical compounds, but mixtures of two or more alloys with uncombined zinc and copper. The alloy with 38·38 per cent. of copper appears to be fairly uniform. Different observers disagree as to the amount of heat produced by any reaction, but the excess of calorics in a zinc reaction over those in a copper reaction appears to be fairly constant. Starting with 640 calories, the value, according to Galt, when copper is dissolved in nitric acid of specific gravity 1·360, we should have 1,357 calories when zinc is dissolved, provided the chemical action is the same in each case. All the calorimetrical results from the different specimens of alloys would theoretically lie upon the straight line drawn between 604 and 1,357. This is practically so from pure copper to the copper 70 per cent. alloy, but beyond that there is less heat produced than that indicated by the straight line law, the maximum deviation being at about copper 37 per cent. The specimen containing 38·38 per cent. copper, which is not far from the alloy $CuZn_2$ shows a loss of 32 calories. The only way in which this deficit can be accounted for is by supposing that the action of this alloy on nitric acid produces a larger quantity of nitric oxide than in the case of pure copper. But allowing full force to this argument it cannot account for as much as 10 calories of the deficit. There is, therefore, a residual deficit as yet unaccounted for on chemical grounds. The author states that it is desirable that experiments should be conducted on the zinc-copper alloys with solvents which give a simpler chemical action than that produced by nitric acid.

The CHAIRMAN pointed out that the results obtained by Galt for an alloy, which appeared to be a chemical compound, were in close agreement with what would be expected from the existence of the Volta contact force.

Prof. ARMSTRONG said that the action of nitric acid on brass or zinc and copper was a function of the quantity of acid present, its strength, the temperature, and the pressure, and that therefore it was unsatisfactory to conduct experiments using nitric acid as a solvent. He suggested the use of a solution of bromine, in which finely-powdered zinc, copper, and brass are easily soluble with a simple chemical reaction.

Mr. TOMLINSON pointed out that it was impossible to use the ordinary formula for the calculation of the Volta effect from the heat of formation of alloys, unless we know exactly the chemical composition of the alloy which is produced.

Mr. W. R. COOPER, referring to Mr. Tayler's Paper, said it was difficult to see that anything could be proved by the application of the Kelvin theory to a metallic contact unless there is ground for believing that some particular alloy of fixed composition is always formed. There is also a further difficulty in converting heat of formation into E.M.F. in cases where the metals have different valencies, for there is no reason why one valency should be selected rather than the other. Referring to Dr. Gladstone's Paper, Mr. Cooper said that it was possible that the difference in the reducing powers of mixtures and alloys might be due to local action, which would be more pronounced in the case of alloys. More hydrogen would be evolved and the reduction would be more complete.

Prof. S. P. THOMPSON then showed an

"Electromagnetic Experiment."

A circular coil, capable of carrying a strong current, was placed with its axis horizontal in a tank of water. Into the tank were also placed some small magnets in sealed glass tubes so adjusted as to have a density approximately equal to that of water. The magnets just floated or just sank. On running a current through the coil it was possible to "fish" for the magnets, which, acted upon by the magnetic field, immediately made their way to the coil. When the current was carefully reversed, upon the approach of a magnet repulsion took place instead of attraction, and the magnet retreated. In general, however, reversal of the current produced reversed polarity in the magnet, and attraction still persisted.

The Society then adjourned until May 25th.

THE ELECTRICAL EQUIPMENT OF SHIPS OF WAR.*

BY C. E. GROVE.

(*Continued from page 129*).

Boat-hoisting Engines.—A British battleship carries two sets, one on either side, of such power that each set can lift by means of tackle a boat weighing 18 tons at not less than 20ft. per minute. This is a favourable case for electric driving, and in the latest British ships electric motors are specified for the work. The actual net horse-power for the lift is approximately 24, and as the motors have to drive through a worm gear and a wire-rope tackle, the maximum input may be taken at about 50 B.H.P. The motors are specified to run at not more than 750 revs. per min., to be watertight, and to be fitted with reversing switches and automatic brakes. The rating of the motors is determined by the temperature limit of 80°F. rise after one hour's run at full load; which enables the weight of the total equipment to be about the same as that of the steam hoist An electric compound deck-winch, as fitted in the United States battleships "Kearsage" and "Kentucky," is illustrated in Fig. 31.

Coal Hoists.—These machines (of which two sets are carried) are of the same class at the boat hoists, but work at a quicker rate. The latest British specifications define their work to be the lifting of 1 ton at 250ft. per minute, but on test they have to lift 1½ tons at this rate. On the test load they have to exert 25 actual H.P., and though the efficiency may be a little higher in this case than in that of the boat hoists, the total input will be 40 E.H.P. to 50 E.H.P. The motors, therefore, may well be of the same size; they are governed by the same specification as to temperature limit, control, &c. The weight of the motors and gears will probably be a few hundredweights more than that of corresponding steam hoists.

Ash Hoists.—One of these is usually fitted to each boiler-room; the "Albion" carries five. Their work is not definitely specified, but may be described as lifting with wire-rope tackle a bucket of ash weighing, when full, about 1½ cwt., at from 200ft. to 250ft. per

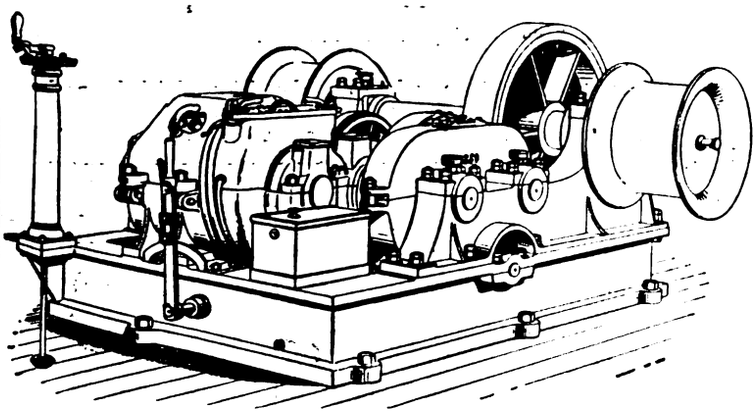

FIG. 31.—Electric Deck-winch, U.S.S. "Kearsarge" and "Kentucky" (General Electric Co., U.S.A.).

minute = 1½ actual H.P., the maximum I.H.P. of the steam engines being about five on a weight of 14cwt. Being placed on the boat deck, machines of this class may well be electric, and as the motors will run at higher speed than steam engines no increase of weight need be involved.

Ventilating Fans.—These are employed for ventilating all compartments below the protective deck and some of the compartments above that deck, such as mess and living spaces. The general practice up to 1898 was to provide six 5ft. 6in. double-breasted steam fans on lower deck, three at each end of ship, driven at a maximum speed of about 400 revs. per min., and connected together to main ventilating trunks, besides an auxiliary system of ventilation with one 4ft. 6in. fan at each end of the ship. The electric driving of ventilating fans is now common in most navies. Fig. 32 shows a Sturtevant fan with open-type motor as used in the United States navy. In a few recent ships, electric fans of from 3ft. to 4ft. diameter have been fitted taking about 7 H.P. at 600 to 700 revs. per min., the same number (8) being employed and connected to the same system of trunks as designed for steam fans. Figs. 33, 34, and 35 show a 3ft. 9in. electric fan of this sort designed by the author and fitted in the I.J.B. "Shikishima." These fans have been adjusted to deliver 7,500 cubic ft. of air per minute, each at 2in. pressure at 480 revs. per min., at which output they consume 5 E.H.P. apiece, but their speed and output can be increased if desired. Experience has shown that the matter of ventilation has been somewhat overdone in recent years, such powerful fans being seldom worked at their full speeds and powers. Accordingly, in the latest British ships—*i.e.*, all designed since 1898, a larger number of smaller fans with shorter and simpler trunks are employed. The "Duncans," for example, will each carry 14 fans not exceeding 24in. in diameter, with motors of about 2 B.H.P., delivering 1,500 cubic ft. of air per minute at 2in. pressure.

Air Compressors for Torpedo Work.—A modern first class battleship carries usually four sets, each capable of delivering 30ft. of air compressed to 1,700lb. per sq. in. in 70min. This involves an average B.H.P. of about 50 to 60 per set of pumps on a little less than three tons weight. Electric compressors would involve quite a different design, but would result in much quieter and smoother working. The weight would remain approximately the same.

Workshop Engine.—This is a small engine of about 5 H.P., driving one or two short lines of shafting actuating half-a-dozen machine tools in the engineers' workshop. It is an obvious case in which electric driving is handier than anything else.

Gun-working Mechanism.—A modern battleship, mounting two pairs of large guns *en barbette*, carries quite a nest of machinery for

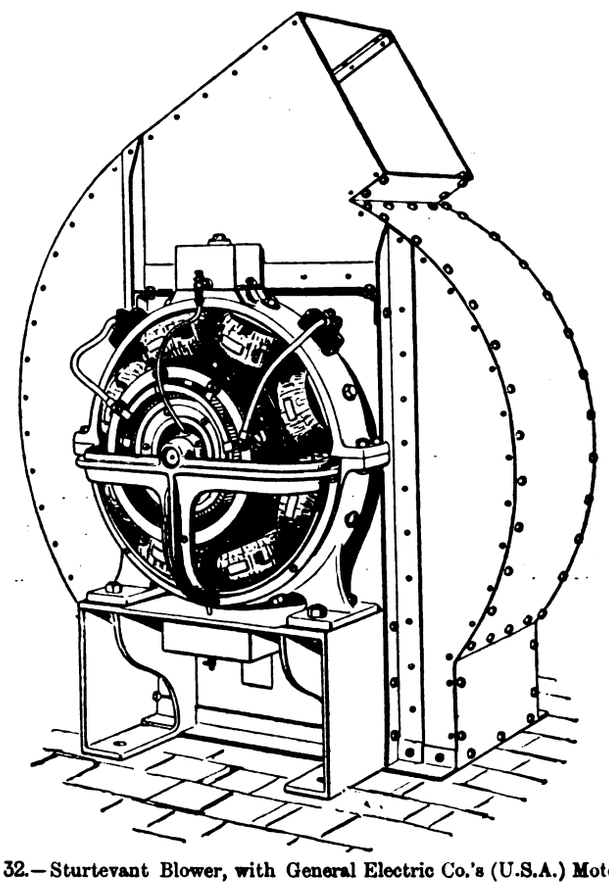

FIG. 32.—Sturtevant Blower, with General Electric Co.'s (U.S.A.) Motor.

working the guns. There are engines for training the turret, independent engines for each gun for elevating and depressing and for running in and out, rammers for loading, hoists for bringing up powder and shell from the magazines below, besides lifting and traversing gear for transporting shot and shell from the bins in the shell-rooms to the handing-up cage. Some of the machines are duplicated and some triplicated, and there are always in conjunction hand-gears for continuing the work if the mechanism fails.* In a ship carrying hydraulic mountings the power is supplied by a steam-hydraulic pumping engine of about 250 I.H.P. situated below and adjacent to the barbette. A pump in the barbette itself is used for circulating the water in the pipes under pressure for use over and over again if the pumping engine below is out of use. The hydraulic supply to each barbette is interconnected with that to the other, pipes running fore and aft along the ammunition passages below the water-line. Hydraulic power has been almost universally used in our navy for the last 20 years. Steam is used a good deal in the United States Navy, possibly because their ships have to operate in latitudes where extremes of temperature are common, and where, therefore, hydraulic appliances are liable to be disabled by freezing. But steam has great disadvantages for the purpose. The working being intermittent, there is great difficulty in starting owing to condensation, and there is further the serious liability to injury to the steam-pipes in action, with possibly disastrous results to the gunners.

* Paper read before the Institution of Electrical Engineers, April 26th.

* Illustrated descriptions of the turrets and gun-mountings of several British and foreign ships are given in a Paper entitled "The Rise and Progress of Rifled Naval Artillery," by Sir Andrew Noble, K.C.B., F.R.S. (*Proc.* Inst. Naval Architects, 1899).

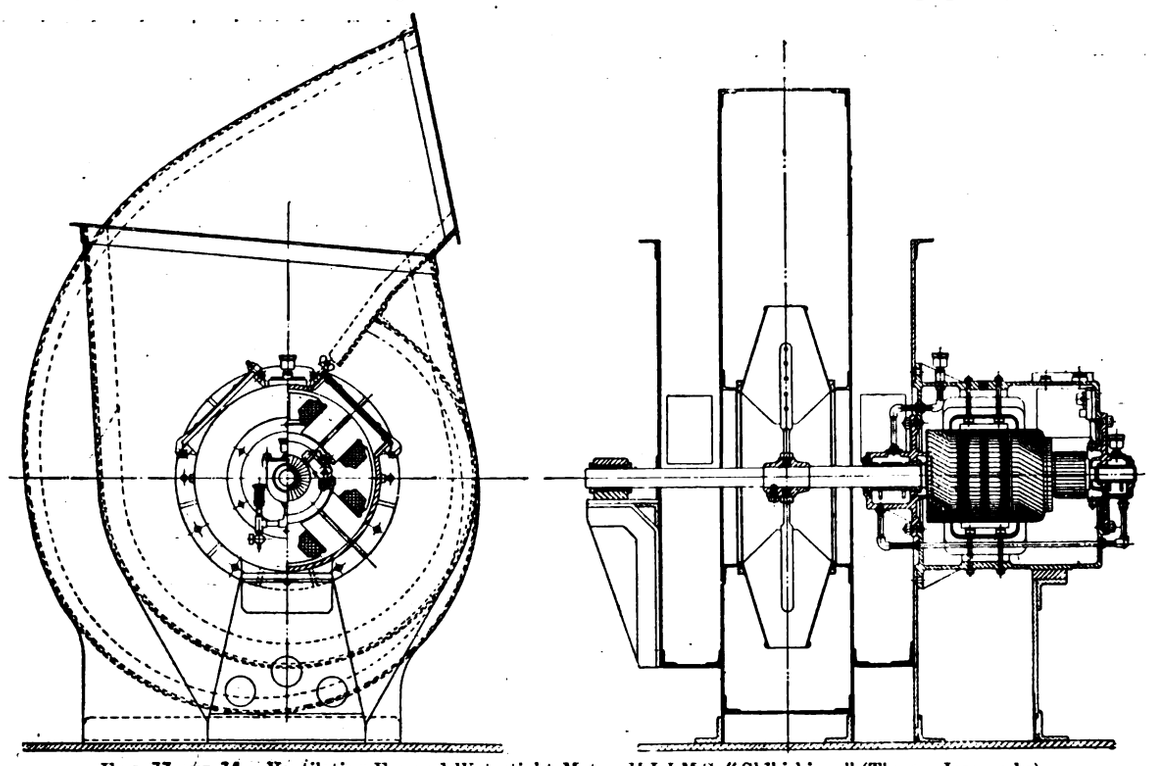
Electricity has come to the front in recent years as a rival to the older hydraulic system. By the English Admiralty it has scarcely been used at all. In the "Majestic" class of battleships electric motors have been put in as an auxiliary for training the turrets, but



FIGS. 33 AND 34.—Ventilating Fan and Watertight Motor, H.I.J.M.S. "Shikishima" (Thames Ironworks).

these are small-powered machines intended only as a help to the hand-gear, the primary installation being hydraulic. A beginning was also made in cruisers by applying electromotors to the 9·2in. guns of H.M.S. "Terrible." In the Japanese battleships fitted with Elswick armament an auxiliary electric training gear is carried, but the motor is about 15 H.P. capacity, and is able to train the turret at the rate of about 2deg. per second. The pump referred to above is also electrically driven. In the United States Navy electricity has been more largely used, and, as compared with steam, earned in the late war good reports in respect of quickness of action and precision of control. The "Brooklyn," which carries two 8in. turrets superposed on two 13in. turrets, had two turrets trained by steam and two by electricity, which favoured a direct comparison. The electric turrets are said to have been started and stopped 37 times in a minute and to have been capable of very small motions at a time. The success of the electric motors in the first ships led to their extended use in later ships, and in the "Kearsage" and "Kentucky," not merely are the turrets trained, but the guns are elevated and the ammunition hoists and rammers worked by electric motors. At the present time there seems to be a

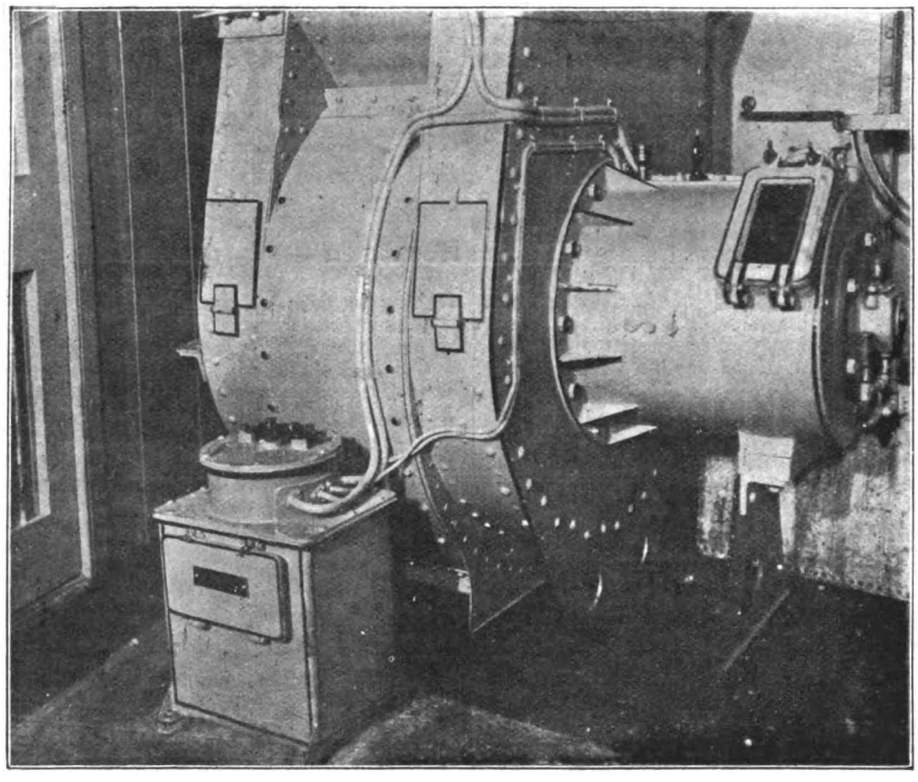


FIG. 35.—General View of Motor Fan and Controller, H.I.J.M.S. "Shikishima."

Digitized by Google

revulsion of feeling against electric installations. Lieut. Norton (speaking apparently on behalf of the American constructors) said * that in the new large triple screw ships being designed for the United States Navy it has been decided not to use electrical power in the turrets except for the hoist, for the reason that "you can tell what is the matter with a steam or hydraulic engine instantly; but you may chase for hours to find a broken circuit, and by that time the action is over and you are out of the deal." To understand this remark the difference in the character of American and English installations must be borne in mind.

For controlling turrets the Americans use an ingenious method devised by Mr. Ward Leonard, which may be fittingly mentioned here. In the turret is a motor (or a pair of motors in parallel) separately excited at constant voltage; its armature is directly connected with that of a generator in the dynamo room, which is steam-driven at constant speed in a field of which the excitation can be varied from maximum to zero, reversed and increased to a negative maximum. The voltage of the generator accordingly varies as its field varies, and the motor armature receiving this varying voltage while its field remains constant, its speed will vary in a corresponding manner. The regulation of the generator field is effected from a controller under the sighting-hood in the turret. The control is said to be extremely sensitive and precise. Retardation is effected with smoothness and rapidity by dropping the excitation of the generator to a point which gives a voltage below that corresponding to the speed at which the motor is at the instant moving; the latter immediately begins to generate current, and therefore quickly absorbs the kinetic energy of the turret. In the latest ships the current so generated is taken up on a braking resistance.

Most nations are now employing electricity to greater or less extent in turrets. Even Sweden is building cruisers in which the working of the turrets and guns is entirely electric. Among the best examples of electric turrets are those designed by M. Canet,† and built in France for many Governments. The essential feature of M. Canet's design is that the turret is, as a whole, primarily designed for electric working. He arranges that the centre of gravity of the moving mass should as nearly as possible lie in the axis of rotation. This ensures moving with minimum power. In the Chilian "Capitan Prat," for example, a 9in. turret, weighing 87 tons complete, was rotated by a 15 H.P. motor at two thirds power, and could be turned by four men through 270deg. in 107sec. It could be moved through one-fifteenth of a degree at a time. If electric power is to render its best services in connection with ordnance work, it seems pretty clear that the turret must be designed throughout for electric working To tack electric motors on to an unbalanced turret designed for hydraulic working is not the way to success. If the turret be fairly balanced, a great saving in power, weight and complexity might be effected by employing electrical gears. Of course a large margin of power and strength are needed to ensure the successful operation of the turret when the ship takes a list in a rough sea or while turning; but, allowing for this, it would seem that the aggregate power, if everything were electrical, might be of the order of 100 B.H.P. normal to 150 B.H.P. maximum under worst conditions. Allowing 250 B.H.P. maximum in motor capacity to provide for duplication where possible, the motors with their gears, switches, and connections would certainly show a saving of 5 tons to 10 tons per turret on the aggregate weights of the hydraulic cylinders and gears, while the weight of the main hydraulic engines and transmission pipes (about 25 tons) would be a set-off against the weight of the electric generators.

(To be concluded.)

THE CALCULATION OF DISTRIBUTING SYSTEMS OF ELECTRIC TRACTION UNDER BRITISH CONDITIONS.‡

BY H. M. SAYERS.

The design of electrical distributing systems in this kingdom has been practised hitherto almost exclusively for electric lighting purposes. The short daily duration of the heavy load and small annual load factor obtained in most cases induce economy in capital expenditure, and the current density at times of full load is restricted by considerations of pressure variation, rather than by losses in the conductors. The conditions of working electric tramway systems are so different that calculations of another order come in, and very materially affect the design of the conductors when highest total economy has to be studied. The principal special conditions are as follows:—

1. The high load factor—due to the fact that a large output is called for throughout the whole of the working hours, which are usually from 15 to 18 per day in the United Kingdom. There are daily "peaks" and seasonal peaks but the hills and valleys are of much less extreme character than those observed on a lighting system.

2. The permissible variation of pressure is much greater. So far as the working of the line is concerned, the only limitation is that sufficient pressure be given at every point to enable the cars to keep schedule time. At the speeds allowed in this country, and with the motors usually fitted, a variation of 10 per cent. of the normal pressure causes no inconvenience.

3. The unsymmetrical arrangement of the two conductors, as between the outgoing or insulated positive conductor, and the return earthed negative conductor. In the great majority of cases, the rails forming the negative or return conductors are of such large section that no other conductors are needed on that side of the system whether for economical or pressure regulating purposes—so far as the working of the line is concerned. But for the protection of other property, the extreme potential difference allowed to exist between different points on the rails is limited by the Board of Trade to 7 volts, and the proportion of current allowed to return through the general mass of the earth to an earth plate at the generating station must not exceed 5 per cent. of the average load or 2 amperes per mile of line. Hence, on a tramway or railway using the rails as return conductor, while the positive conductor should be designed with regard to ordinary considerations of economy and efficiency (including the fact that practically the whole of the pressure drop will occur on that side of the system); the negative conductor designed primarily to satisfy mechanical conditions in most cases accidentally happens to afford much better conductivity than the positive conductor, and yet its conductivity has in many cases to be supplemented in order to satisfy the regulations imposed by a benevolent Board of Trade. It will be seen below that the determination of these auxiliary return conductors can be arrived at by calculations similar to those controlling the choice of the positive conductors, but that some of the factors have different values, and their load has to be estimated in a different way.

One effect of these special conditions is that the use of conductors designed for lowest total working cost is practicable in many electric traction systems. The well-known consideration that the total working cost of a conductor during any given time is the sum of two items, one being the value of the power wasted in it, and the other a percentage of its original cost at some annual rate, indicates at once that for a higher load factor a conductor should be worked at a lower rate of loss, or in other words at a lower current density. To determine the most economical current density in a given case, values are required for the following factors:—1. The money cost of the cable to be employed expressed in terms of the amount of copper in the cable, say the price in pounds of a ton of copper, insulated, sheathed and laid $=p$. 2. The percentage of the cost of the cable which must be annually set aside to provide for interest, maintenance and depreciation $=$ R. 3. The average number of hours per day taken throughout a year that the cable will be under load $=h$. 4. The load factor of the cable during the time it will be under load. If the load will be steady, the value of this will be unity. If the load will vary in a known way, the load factor will be the mean square value of such variable load referred to a steady load of its maximum value as unity, and can be calculated from a prophetic load diagram, and in the case of such variable load the most economical current density given by the calculations will correspond to the square root of the mean square value of the current. In what follows, this load factor will be taken as unity. 5. The cost of a Board of Trade unit generated and delivered to the conductor in pence $=n$.

From 3, 4, and 5 the cost per annum of a watt wasted in the conductor can be calculated, or inversely, what number w of watts wasted in the cable will cost, say, £1 per annum, and the two quantities representing the total cost per annum reduced to a common measure. In Perry's "Calculus for Engineers,' page 55, the question of economy in electric conductors is used as an example in maxima and minima, and I have found the method there indicated convenient for practical use. Prof. Perry there shows that the waste in watts or ohmic loss, and the constant loss or interest loss, can both be simply expressed as functions of the resistance of a conductor, assuming a certain current and certain length, and that their value may be written: $y = \mathrm{C}^2 r + \frac{t^2}{r} + b$. Where $\mathrm{C}^2 r$ is ohmic loss, $\frac{t^2}{r}$ is the interest item—expressed in watts, and b is a constant which depends upon factors not affected by the size of the cable laid.

In Appendix No. 1 Prof. Perry's expression is worked out at length, and the result shown that the most economical current density $\frac{\mathrm{C}}{\mathrm{A}} = \sqrt{\frac{\mathrm{R}wpm \cdot 045}{100}}$, where C = amperes, a = cross-section of cable in square inches (so that $\frac{\mathrm{C}}{a}$ = amperes per square inch) and m = tons of copper in a mile length of one square inch

* Discussion on Admiral Melville's Paper, "The Logical Arrangement of the Motive Power of Warships," Inst. N. A., March, 1899.

Digitized by Google

section, R = annual rate per cent. for interest, &c.; w = the number of watts wasted continuously during working hours, which will cost £1 in a year's working, and p = the price in pounds of a ton of copper in the form of cable. ·045 is resistance in ohms of a mile of copper of one square inch cross-section, the weight m of which is 9·1 tons. In Appendix No. 2 an example is worked out numerically and tables are shown giving values obtained by taking figures within probable practical limits. The method of calculation here used is, of course, perfectly general, and applies equally to low-tension, high-tension, continuous and alternating currents, however fed to the conductors. The cost per ton of copper in cabled form will, of course, vary widely with the way the cable is to be used, the working pressure, and other conditions; for example, a triple twisted cable for three-phase currents will be much more costly per ton of copper than a concentric cable for continuous currents, working pressure and material being equal. It has also to be carefully noted that the value of the Board of Trade unit to be used is that of the unit delivered to the conductor system under consideration, and if the energy has to be transmitted or transformed before such delivery, the cost of generating the unit has to be "loaded" with the cost of such transmission or transformation, including the interest, maintenance, and depreciation cost of transmitting or transforming system. For example, the most economical density in a low-tension system fed from transformers is lower than in a low-tension system fed direct, assuming that the generating stations in the two cases supply energy at equal costs. It must also be recognised that power wasted (or used) in distribution costs as much as power used in the motors. For cables of a given construction and for use under given conditions, it will generally be found that the average price per ton of copper taken from makers' prices through such narrow ranges of size as are usually employed on a given system is sufficiently accurate. Where a very wide range of size is called for it may be worth while to calculate separately for the larger and the smaller cables.

The question of systems of laying cables and the cost thereof is not considered here, as the choice of the methods to be used depends much upon various local conditions, and the cost per mile is very little affected by the size of the conductor laid. It may be worth while to suggest, however, that the cost per ton of copper of a cable armoured for laying direct in the ground is higher than that of a similar cable sheathed for drawing into pipes or conduits, and as the allowance for depreciation and maintenance of pipes and conduits is a good deal lower than that for cable, economy may frequently be best studied by the use of a "drawing-in" system. The facilities for renewal and repairs and for replacing cables by others of larger size if required, are advantages not to be lightly ignored, and the conditions on electric traction systems enable these advantages to be utilised to a degree that does not obtain in some other services. The calculation of best sizes for track feeders is exactly that above described, but in most cases a higher value has to be taken for the wasted energy, *i.e.*, w in the equations is smaller. This leads to the use of a lower density in such cables or to a larger provision of copper for the current to be carried. The reason is that in most cases a "negative booster" has to be employed in connection with such a feeder, and the energy wasted has to be loaded with the loss in transforming, and the capital charges on the apparatus. The booster may be considered a part of the feeder, and as its size and the losses in it are proportional to its output, they are properly brought into the calculation by charging a higher price per unit delivered to the cable. Appendix No. 3 gives some examples of such calculations, and is also applicable to trolly feeders in which "boosters" are employed to keep up the voltage at the distant end. Considering the figures given in the tables, it will be seen that the limiting distance due to loss of pressure in feeders designed on economical principles is reached at from two to three miles from the generating station. The density of the traffic does not affect this limit. The cost of energy does affect it, and in such a way that the lower this cost, the shorter is the range of economical distribution because the economical density being higher, the limiting drop of voltage is the sooner reached. But it may be worth while in any particular case to use heavier conductors and so extend the working radius of a station, because the cheaper generation of power at that particular place more than compensates for the increased distribution costs. It may happen also that the use of heavier mains for the more distant parts of the system may prove to be cheaper than any other means of keeping the pressure up on those parts. It is a useful feature of the methods of calculation herein described that they indicate in a facile way the results of any departure from the theoretically best conductor sections, and so provide at least part of the data for determining the best system to adopt.

When the distribution radius much exceeds the distances above named, it will be obvious that the single station supplying direct to the feeder system becomes impracticable, and it is under these circumstances that an engineer is called upon to thoroughly investigate the alternatives, and estimate the total annual cost of working the lines by means of each of such alternatives. Only certain systems in practical use in the United Kingdom can be mentioned. They are—1. The multiplication of generating stations retaining the direct-current low-tension system of generation. (2) The use of battery sub-stations charged from a single generating station. (3) The use of a single generating station, generating polyphase currents at high pressure, and transforming sub-stations placed at suitable points on the line, supplying low-tension direct current to the line feeders. The direct current for the lines near the station may or may not be generated by special direct-current sets: when it is, separate consideration has to be given to such contiguous area, in calculating conductors and costs.

The second system above mentioned has but few examples, and reliable data are somewhat difficult to obtain. Its application would seem to be limited to cases where an infrequent service is given on distant lines; hence the feeders having to carry but a small average current, their size may be kept down, and the battery provides for the larger current needed by the cars. It will be obvious that the arrangements require to be carefully thought out in order to ensure the battery being properly charged, and always available during service hours. A very good example is that designed by the late Dr. John Hopkinson for the Leeds tramway, and described in Prof. Ernest Wilson's "Electrical Traction." It will be found that some complication is involved. Considering the present limited application and the many questions of detail involved in calculating the working cost of such arrangement, the system cannot be discussed now, and is mentioned as a practical means of meeting the demand which may be sometimes made for working a long branch, the traffic on which only calls for a sparse service, or on which the traffic is relatively heavy for only a small portion of the working hours. The discussion will be narrowed down then to a comparison of the first and third alternative systems, involving a statement of the data which affect the choice and the calculations by which the working cost of each may be estimated with an exactness dependent upon the accuracy of the figures adopted. As some of these figures must themselves be estimated, the judgment and experience of the engineer are here very important factors.

It is quite clear that there are two broad questions to be decided, firstly, What will be the total cost of producing a unit at the station or stations? and secondly, What will be the total cost of getting a unit to the car? in each case. The first question involves the charges on the capital cost of the station plant in addition to the working expenses, and the second question involves the efficiency of the distributing system as well as the capital charges upon it, as the cost of delivering a unit includes the energy wasted in its distribution. "Used in distribution" seems a more rational expression than "Wasted in distribution," but the latter phrase is so widely adopted that confusion might result from an attempt to reform. It is obvious that by the multiplication of directly feeding generating stations *ad lib.* the loss in distribution as above defined may be reduced to any desired extent. On the other hand, with a system involving transformation there is some minimum loss which cannot be reduced, and which corresponds to the attainable efficiency of the transforming devices. Clearly, then, this minimum loss constitutes a handicap upon the multiphase high-tension system which must be overbalanced by other advantages in order to justify its adoption. The reduction in the cost of generation of energy due to the employment of large units in one large station as against smaller units in a number of stations can only be estimated in advance by a complete study of local conditions guided by experience and judgment. Cases arise, of course, where it is clear that a station at a particular place enjoys such a great advantage as regards cost of fuel, abundant available condensing water, and freedom from neighbours who may object to noise and vibration, that direct and indirect costs must be much lower than in any other available site. The greater economy in staff and in total value of plant and buildings to be obtained by generating at one station instead of several can be estimated very fairly. A more difficult item to estimate is the relative value of the land.

Whilst every case requires special study to determine what advantage in generating costs is attainable by the adoption of the single large station, a study of the distribution costs can be made on general principles, which will indicate what that saving must be in order to give the single station a balance of advantage.

The limit of direct-current supply has been assumed to be the distance at which the drop in the trolley wire is 50 volts, *i.e.*, 10 per cent. of the energy given to the cars. Assuming a uniform distribution of the cars, this means an average drop of 5 per cent. over the whole system. (Notice that if the system is one radiating from a large town, so that the cars are more dense near its centre, the average drop will be less. It can be calculated as closely as the service can be predicted.) The loss in track feeders will be less; probably 2½ per cent. will cover it in most cases.

This total loss of power in distribution, amounting to 7½ per cent. of that delivered to the cars, can be attained with generating stations spaced from four to six miles apart, *i.e.*, delivering power, each for a radius of from two to three miles. As the interest item of distributing cost equals in value that of the loss of power item,

Digitized by Google

it follows that distribution costs in such a system = 15 per cent. of the value of the power delivered to the car, and the total cost of 100 B.T.U. at the cars = that of generating 115 B.T.U. The plant has to be proportioned to produce 107½ per cent. of the energy delivered to the cars, as its normal full load. In a multiphase transforming system, the overall efficiency cannot at present be taken at more than 80 per cent. Mr. Parshall has given figures from Dublin experience showing somewhat lower rates, but 80 per cent. seems attainable. Then the generating stations will have to supply 125 units per 100 units delivered to the cars. The interest and operating costs of the distributing system cannot be calculated so simply in this case as in the former, as moving transforming devices calling for human attention are involved ; but if the prices of those devices are known, and a proper rate of interest calculated to cover depreciation, the cost of attendance and sites can be got at pretty closely, and a price worked out per unit delivered to the mains which can be expressed as a percentage rate of loss of the energy delivered. If this is called N, we have the following expression showing at what proportionate cost the high-tension station must generate energy to counterbalance the larger distribution losses. $\frac{b}{a}=\frac{115}{125+N}$, where b equals cost of production at the single high-tension and a = cost of production at the multiple low-tension stations. Unless $\frac{b}{a}<\frac{115}{125+N}$, the low-tension multiple station system will give the lower working cost. For this calculation to be of any practical value, it is evident that the cost of production must be properly debited with all charges in each case. To make such an estimate for prospective stations with a near approach to accuracy is a task much more difficult than calculating conductors, but an incorrect decision as to the system to be preferred in a given case is not probable if experience and judgment are brought to bear on a careful investigation of the local conditions. The value, N, above taken includes the interest item on both the high and low-tension conductors. This value can be found as in the other case, and will, as in that case, be equal to the ohmic loss in each ; but it must be noted that the cost of a watt is greater in the low-tension conductors owing to the transforming loss. The best density in the high-tension conductors is found exactly as in the case of direct supply, but the cost per ton of copper will be considerably higher in the case of the three-core high-tension cable, and hence the best density will be higher. The interest and operating costs of the transformers must be carefully considered, proper allowance being made for the necessary spare plant and margin of power necessary.

If these costs come to d pence per unit, the condition of advantage for the high-tension system is

$$\frac{b+d}{a}<\frac{115}{125+p},$$

where p is the percentage value of the losses in the high-tension conductors. This will usually be small, not over 5 per cent., and taking this value we get

$$\frac{b+d}{a}<\frac{115}{130};$$

so that for equal costs under the two systems

$$b=0\ 885\ a-d\ ;$$

or in words, the cost of generation at the single high-tension station must be less than 88½ per cent. of the cost at the low-tension stations by the cost per unit of interest, attention, and stores due to the transformers. If $b<0{\cdot}885\,a-d$, the difference is the saving per unit to be made by the high-tension system ; if $b>0{\cdot}885\,a-d$, the difference is the advantage for the low-tension system. Using correct data to suit the case, a very good judgment can be arrived at as to the most economical system to be adopted, and it is suggested with much confidence that such calculation is a safer guide than a general statement that for a traction station of over so many thousand horse-power this or that system is the only commercial one. It seems to be overlooked sometimes that the cost per unit at the car, and not at the switchboard, is the commercial criterion, and that to attain a lower figure at the car the cost of the unit at the switchboard must be very considerably lower in the case of any system using moving transformers than in alternative arrangements.

The choice of a site for a generating station may greatly affect the generation costs, and as these materially influence the design of the distributing system, the importance of careful choice of site or sites is very great, and in any contemplated electric traction system this should be one of the earliest matters submitted to and decided by the engineer. Whenever possible, eligible sites for compulsory purchase should be scheduled in the order authorising the line. The points affecting the choice are foreign to the subject now discussed and a certain cost per unit at the switchboard will be herein assumed, the sole subject considered being the delivery of the power to the cars at minimum cost under the conditions imposed. The economical use of the power on the cars is also foreign to this discussion, but it cannot be seriously contended that waste on the car excuses avoidable waste in the distributing plant. The consideration of a particular case will best illustrate the application of the foregoing principles. Diagram A is a scale plan of a tramway system, all single lines with turnouts. The proposed service results in a distribution of cars as marked in figures along each section of the line. The total number of cars is 57. The average current taken by each car is reckoned at 15 amperes. Hence the average power demanded at the cars will be

$$\frac{57\times15\times500}{1{,}000}=427{\cdot}5\text{ kw.}$$

At T is a site available for a power-house. The extremes as regards distance from T are A 7·1 miles west, H 5·2 miles east, and L 7 miles south-west of T. There is, however, a shorter route from T to J than by the tramway, and this route being available for a feeder cable reduces the distance TL to about 4·35 miles, and facilitates feeding at J, which it will be seen is an important centre. In natural order one should first consider the use of T as sole generating station for the whole system, find the most economical current density, and see whether the drop permits of low-tension generation and direct feeding (Diagram B).

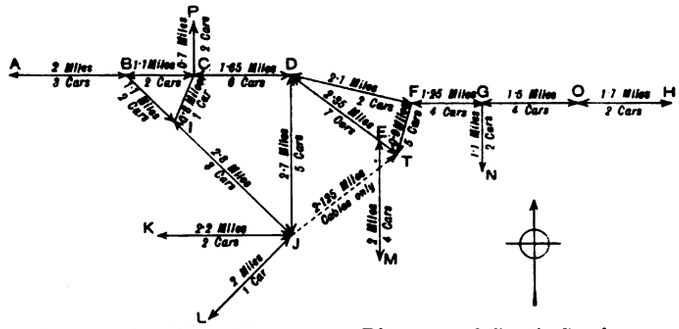

DIAGRAM A.—Plan of Tramways. Distance and Cars in Service.

For the purpose of this example the following figures are used :—

Annual charges on cost of cable for interest and depreciation, 7 per cent. or R = 7.

Annual hours of use, say 15 × 365 = 5,474.

Cost of energy per B.O.T. unit at switchboard n = 75d.

Tons of copper per mile run of 1 sq. in. cross-section = m = 9·1.

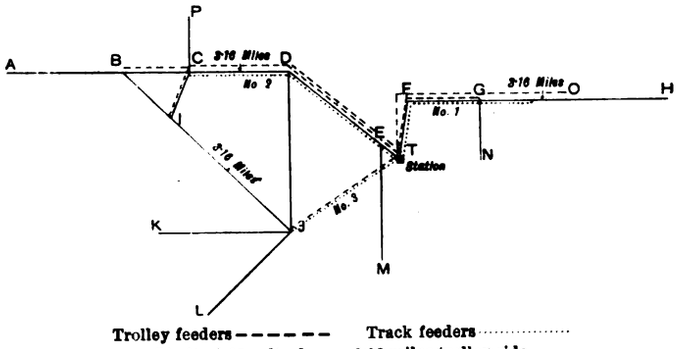
Cost of insulated cable per ton of copper p = £151.

Watts continuously lost worth £1 per ann. $=w=\frac{240}{5{\cdot}475}\times0{\cdot}75=58{\cdot}45.$

Then, by formula given in Appendix No. 1, we have

$$t^2=\frac{\text{R}.w.p.m.0{\cdot}045}{100}=\frac{7\times58{\cdot}45\times0{\cdot}045\times9{\cdot}1}{100}=251,\text{ or } t=15{\cdot}8\ ;$$

say $\frac{t}{0{\cdot}045}=352$ amperes per sq. in. is thus the most economical density in this case. The voltage drop per mile is 15·8. Hence the drop from T to A would be 15·8 × 7·1 = 112 volts, and from T to H



Trolley feeders - - - - - - Track feeders .....

Limit of 50 volts drop = 3·16 miles trolley side.
Limit of drop in rails, 5 volts = 173 amp. miles.

DIAGRAM B.—Low Tension, Single Station.

15·8 × 5·2 = 82 volts. These are too great for good working, and, taking 50 volts as the limit, the distance limit is $\frac{50}{15{\cdot}8}=3{\cdot}16$ miles.

Beyond this limit there are 15 cars west and three cars east of T, so that two-thirds of the load comes inside the permissible drop, and should be supplied by directly-fed cables. The remainder should be fed by "boosted" cables. No allowance is made for the conductivity of the trolley wires excepting where they suffice without cables in parallel, and there two No. 0 wires of 0·162 sq. in. combined section are reckoned on. It is found in practice that in a tramway system calling for several feeders it is better to work the trolley wire in separate sections, each being fed by a distinct feeder. This results in the rapid localisation of short circuits of all kinds and

Digitized by Google

minimises disturbance to traffic. It also facilitates the proper loading of the individual feeders and gives valuable information to the power-house staff as to the distribution of the load.

The losses in the feeders to the directly-fed portions of the sample system will be approximately as follows:—The cable TJ has to carry 98 amperes 2·125 miles ; the average length on the branches beyond J over which the power will be distributed is, say, one mile total from T 3·125 miles. The branches JD and JI will only be fed viâ J to points equidistant from T by the other routes, and on all these branches the trolley wires suffice without cable. The remainder of the current from T within the area is supplied by cables accompanying the line, and for the purposes of this approximate calculation it may be taken that the load is symmetrical along them, so that the average load may be taken as half the total and the loss as that due to half the current carried the extreme distance. (Obviously the loss may be calculated much more minutely than this for any given distribution of cars, gradients, &c.) The current being 532 amperes, half of it is 266 amperes. Then we get total loss in watts—

For current supplied to J $98 \times 3{\cdot}125 \times 15\ 8 = 4{,}820$
And the balance $266 \times 3{\cdot}16 \times 15{\cdot}8 = 13{,}300$

18·12 kw.

As 58·45 watts cost £1 in a year's working, the money cost of this loss will be $\frac{18\ 120}{58{\cdot}45} = £310$ in round figures, and as the interest cost of the cables should equal the total cost of distribution (strictly speaking that portion of the cost affected by system adopted) to the trolley wire, the total cost under these heads for the lines considered would amount to £620 per annum. But the use of the trolley wire where practicable will reduce the cable cost and interest item below this theoretical amount, and a table follows giving the actual feeder cost. Inspecting the plan, it is clear that the junction I is about the centre of gravity of the load beyond the 3·16 miles on the western sections. This is five miles from T, and the load to be delivered is that for 15 cars = 45 amperes. The energy lost in these boosted feeders is more costly, having been transformed by the boosters, whose efficiency is rarely over 75 per cent. The value of the boosted unit must therefore be taken at $0{\cdot}75 \times 1{\cdot}33 = 1$d., the value of w becomes 44 instead of 58·45, and $t^2 = \frac{251 \times 44}{58{\cdot}45} = 189$ nearly, or $t = 13{\cdot}75$ and $\frac{13{\cdot}75}{045} = 306$ amperes per sq. in. as best density.

Drop per mile is 13·75 volts. The boosters would only be necessary to make up the drop in the lengths beyond the 50-volt drop limit, so that this lower density should, strictly speaking, apply only to the excess of cable length beyond 3·16 miles. It will be better, obviously, to use a conductor of uniform section to give the same drop. In the case of the western section then the drop will be $50 + (13{\cdot}75 \times 1{\cdot}84) = 75{\cdot}3$ or 15·06 volts per mile, showing that the refinement makes little difference in this case. On the eastern section the drop will be $50 + (13{\cdot}75 \times 1{\cdot}16) = 65\ 95$, say 66 volts, or 15·3 per mile. The losses will thus be :—

Western 75 $3 \times 225 = 16{,}942$ watts.
Eastern 66 $\times\ 45 = 2{,}970$ „

19,912

(say 20 kw.)

Of this 20 kw , $270 \times 50 = 13{,}500$, the unboosted cost £1 per 58·45 and 6,500 cost £1 per 44, so that the total annual cost of the loss in these feeders will be :—

$\frac{13{\cdot}500}{58{\cdot}45} = £231$ nearly
$\frac{6{\cdot}500}{44} = £148$ „
£379 „

The interest on the mains will be somewhat less, owing to the use of trolley wire on the more lightly loaded branches. To this has to be added an annual charge representing interest, maintenance and running cost of "boosters" to give an output of 6·5 kw. With spare plant 10 kw. might be provided, and would probably cost £20 per kw., say £200. Fifteen per cent. per annum is a proper charge for interest and running expenses on such plant, so that this item would be £30 per annum. The following is a schedule of feeders on the trolley side, wherever needed to supplement the trolley wires :—

Direct Feeders.

Line.	Length, miles.	Amperes.	Section cu. sq. in.	Tons, cu.	Value.
TJ	2·125	98	0·277	5·37	£817
TE	0·35	247	0·700	2·23	337
ED	2·00	165 mean	0·470	8·55	1,290
TF	0·9	187 „	0·531	4·35	655
FG	1·25	120 „	0·342	3·56	538
	6 625			24·06	£3,637

Boosted Feeders.

Line.	Length, miles.	Amperes.	Section cu. sq. in.	Tons, cu.	Value.
TC	4·1	225	0·672	25·00	£3,775
CI	0·9	60	0·179	0·15	23
CB	1·1	75	0·224	0·22	33
TO	3·8	45	0·134	4·63	699
	9·9			30·00	£4,530

Total, £8,167.

The cost of distribution on the trolley side is thus :—

Loss in direct feeders, 18·12 kw., worth annually	£310
Interest on cables in ditto, 7 per cent. £3,637	255
Lost in boosted feeders { 13·5 kw., worth £231 ; 6·5 „ „ £148 }	379
Interest on cables in ditto, 7 per cent., £4,530	317
Annual charges on boosters	30
	£1,291

This works out per unit delivered to the cars :—

$$\frac{1{,}291 \times 240}{427{\cdot}5 \times 5{,}475} = \frac{309{\cdot}840}{2{,}340{,}000} = 0{\cdot}133\text{d. ;}$$

making total cost 0·883d., disregarding losses in the return conductors. But the regulation as to P.D. in rails forbids such disregard, and their effect must now be considered. Assume that the track is single and laid with 90lb. rails, or 180lb. rail per yard of track. Assuming the resistance of the rail to be 11 times that of copper of equal section, and that joints add 5 per cent. to that resistance, a mile of bonded track will have a resistance of 0·0289 w. The interesting Paper read by Mr. Parshall before the Institution on April 28, 1898, will be familiar to all interested in this question, as it shows by examples how the chemical composition of rails, kind of bonding, and number of joints per mile has to be taken into account. Naturally the mechanical use of the rails takes precedence of their electrical functions, and hence the electrical engineer has to be thankful for what he can get. The resistance of the return as laid is usually lower than that of the rails alone, some conduction being afforded by the earth. The amount of this varies very much. Mr. Parshall has found an instance in which only two-thirds of the current returned by the rails. Weather affects it. In one case within the writer's knowledge wet weather reduces the voltage drop, and also the stray current, evidently increasing the conductivity of the non-metallic parts of the track. But as this earth shunting of the rails cannot be foretold, the safe course is to take the resistance of the uninsulated return as that of the rails alone. To allow for possible increase of service, abnormally busy days, and bunching of cars, the limit calculated on should be, say, 5 volts, not the whole 7 volts allowed in the Board of Trade regulations. The integrated product of amperes into mile to give this drop will thus be $\frac{5}{0{\cdot}0289} = 173$ ampere miles. Mr. Trotter's Paper of April, 1898, gives a neat and simple graphic method of showing the drop under given conditions. It can be easily applied along any section of line with a uniform service. For such a case as that under consideration, with varying services along different sections and junctions, an arithmetical process seems a little simpler. The arithmetical process is as follows :— Starting from the station, sum the product of amperes into miles until this product equals the constant corresponding to the limiting drop—*e.g.*, 173 for the case here assumed. It is at once clear that all all current from cars beyond this point has to return by track feeders.

From this point start the integration afresh, and go on until the constant is again reached. At this second point the rails should be at earth potential. Recommence the summation from this second point and go on again to the constant. Then all the current due to cars between the first and third points should return to the station by a track feeder connected at the second point, and so on in succession, the even points marking feeder connections kept at earth potential, the odd points marking points of maximum D.P. above earth in the rail. This calculation applies equally to feeding points in transforming systems, so far as such points depend upon the drop in the return. It will be clear that the direction of the current must be from odd points to even points. When the terminus of a route does not correspond with an odd-numbered point, integrate the ampere miles from the last odd point forwards, and from the terminus backwards, and the point on the line where these sums are equal is the last feeding point, the potential of which may be above that of the earth by the amount corresponding to the defect in the ampere miles from the constant. This means, of course, a little lighter feeder, but the difference is usually insignificant as regards economy.

(To be continued.)

LEGAL INTELLIGENCE.

(*Continued from page 172.*)

Chamberlain and Hookham v. Bradford Corporation.

Judgment in this action is to be given to-day (Friday) by Mr. Justice Farwell.

Cuba Submarine Telegraph Co. (Ltd.) v. West India and Panama Telegraph Co. (Ltd.).

This case, which came before Mr. Justice Farwell on Saturday and Monday in the Chancery Division, raised questions as to the construction of an agreement dated Jan. 31, 1870, entered into between the two companies. Plaintiffs own submarine telegraph cables laid along the south coast of the Island of Cuba and a land line across the western extremity of the Island of Havana, the cables thus connecting Havana with Santiago. From Havana submarine cables, owned by the International Ocean Co., run northwards to Florida, which is connected by a land line with New York. Defendants are the owners of submarine telegraph cables running from Santiago to Jamaica and to nearly all the other islands of the West Indies, and to Georgetown and to Colon on the Isthmus of Panama. By the agreement of Jan. 31, 1870, between the plaintiffs and a company of the same name as defendant company (being the predecessor of the defendant company), it was provided that :—

(1) "The Cuba Co. will hand over to and forward by the West India Co. all telegraphic messages received by or sent through the lines of the Cuba Co. for any other part or parts of the world with which the West India Co. may be in telegraphic communication. (3) The West India Co. will hand over to and forward by the Cuba Co. all telegraphic messages received by or sent through the West India Co. for such places as the Cuba Co. may be in telegraphic communication with. (4) Each company party hereto will forward the traffic and messages received from the other company with all possible expedition, and in case of breakdown of line will repair the same as speedily as practicable, and generally will assist by every means in their power to develop the traffic and business of the other company. (5) Neither company party hereto will enter into any agreement or traffic arrangement with any other company or persons, or be connected with, or interested in, any telegraphic line whatsoever which may be prejudicial to the interests of the other company party hereto without the assent in writing under the seal of such company being had and obtained. But either company shall be at liberty to send messages over their lines at the written request of the sender of such messages, without solicitation or suggestion by any competing lines, provided that in such case the other company party hereto shall share in the amount accruing in respect of such messages in proportion to the amount each company would have received had the messages gone over the lines of both companies. (7) The West India Co. are to be at liberty to place all their wires and cables at Santiago de Cuba in connection with the wires and cables of the Cuba Co., and they are also to be at liberty by their own officers and servants to work all through traffic from any part of the West India system to any place or places beyond Havana without any interruption or interference by the Cuba Co., and the through traffic of the West India Co. is to take precedence and have priority over all the local traffic of the Cuba Co., except as otherwise provided by the terms of the said concession. (8) The West India Co. are to find, supply and maintain the necessary staff at Santiago de Cuba for working not only their own lines but also the Cuba lines, charging the Cuba Co. a fair proportion of the cost of staff at Santiago de Cuba, and the whole cost of staff at the intermediate station or stations, and an addition of 25 per cent. on such cost, their share of the expenses of general management and superintendence."

Plaintiffs alleged that by means of defendants' cables plaintiffs are in telegraphic communication with all places directly served by defendants' cables, and with places beyond with which defendants are in telegraphic communication, and further, that by means of the cables from Havana to Florida, and of the land lines to New York, and of submarine cables from New York across the Atlantic, all places directly served by defendants' cables and places beyond with which defendants are in telegraphic communication with North America and with London and other places in Europe. A new cable has recently been laid between Bermuda and Jamaica by the Direct West India Cable Co., and by such means, and the cables of companies allied with the Direct Co., plaintiffs alleged that competition with the business of plaintiffs and defendants was threatened. The plaintiffs charged that any such arrangement as defendants threatened and intended to make with the Direct Co., whereby messages handed in by the Direct Co. at Jamaica would be transmitted by defendants' lines to places south and east of Jamaica at a rate lower than that charged locally from Jamaica to such places would be an agreement or traffic arrangement prejudicial to the interests of plaintiffs, and that any such arrangement would constitute a breach of clause 5 of the agreement. Plaintiffs claimed an injunction restraining defendants from entering into an agreement or traffic arrangement with any company or persons which might be prejudicial to the interests of plaintiffs without their assent in writing under seal; also an injunction restraining defendants from forwarding any telegraphic messages received by defendants at Jamaica from the Direct West India Cable Co. for transmission to the east or south of Jamaica under an agreement or traffic arrangement which was or might be prejudicial to the interests of plaintiffs, and for consequential relief and damages.

Defendants contended they had never threatened or intended, and did not now threaten or intend, to arrange with the Direct Co. to transmit messages from London handed by the Direct Co. at Jamaica to defendants for transmission to places south and east of Jamaica at a lower rate than the local rate to such places from Jamaica, or to arrange terms with the Direct Co. which should enable the message handed by the Direct Co. to defendants at a rate greater than the through rate which had been fixed with respect of messages from London to places south and east of Jamaica viâ New York and Havana. Defendants had fixed the rate payable for messages transmitted over their lines so that the through rate from London viâ the Direct Co., to a place to the south or east of Jamaica was for the present the same as the present through rate to the same place from London viâ New York and Havana, but they had not done so under or by virtue of any arrangement or agreement with the Direct Co. They alleged that plaintiffs claimed to do, and had for many years done, and were still doing the very thing which they now claimed defendants were not entitled to do. In 1889 a French company, La Société Francaise des Telegraphie Sous Marine, opened for public traffic a system of cables between Santiago de Cuba, Porto Palala, San Dominique, Curaçoa, and Venezuela, and in 1890 they opened cables between Martinique and Paramaribo. In 1891 they also laid a system of cables between Paramaribo, Cayenne, and Vizen, and between Porto Plata and Martinique, and the French company's lines therefore connected Santiago de Cuba (the eastern extremity of plaintiffs' system) with Martinique, Paramaribo, Cayenne and Vizen, and it became possible to send messages from and to New York and London over plaintiffs' system. If plaintiffs should prove successful, defendants, by way of counterclaim, set out that the French company was in competition with defendants, and the agreement or arrangement between plaintiffs and the French company was prejudicial to the interests of defendants, and was a breach of the agreement. They claimed that by reason of such acts defendants had suffered great damage, and counterclaimed an injunction restraining plaintiffs from handing to the French company at Santiago de Cuba any telegraphic messages sent over plaintiffs' lines for transmission to Cayenne or Vizen or any place south of Martinique, except such messages as the sender thereof, without solicitation or suggestion, should in writing request plaintiffs to forward by way of the lines of the French company. They also asked for a declaration that defendants were entitled to a share in the amount of toll accruing to plaintiffs in respect of messages sent over the lines of plaintiffs and handed by them to the French company at Santiago de Cuba for transmission to Cayenne or Vizen or places south of Martinique which the sender might request plaintiffs to forward by way of the lines of the French company. By way of further relief, defendants claimed an injunction restraining plaintiffs from entering into or continuing any agreement or traffic arrangement with the French company or any other company or persons which might be prejudicial to the interests of defendants without their assent in writing.

After hearing lengthy arguments by counsel on both sides,

Mr. Justice FARWELL, in giving judgment, held that plaintiffs were entitled to succeed, but left the form of the declaration to be settled by counsel. He thought that the interpretation put on the agreement by defendants was much too narrow, and would lead to ridiculous results. He thought it was clear that plaintiffs' lines had been intended as a connecting link between the International Ocean Co. and defendants' lines. The general idea was a connection of the West Indian islands with North America. Competition was the keynote of the agreement, and the parties plainly intended that there should not be competition between either of the companies and any other company. His lordship accordingly gave judgment for plaintiffs, with costs.

Mr. HALDANE, for defendants, applied for a stay of execution for 14 days, with the view to an appeal.

The application was granted.

Ashwell and Nesbit (Ltd.) v. Stanton.

This case came before Justices Darling and Bucknill on Monday, on defendant's appeal from a decision of the Official Referee.

Mr. MANISTY, for appellant, said the action was brought by Messrs. Ashwell and Nesbit, Ltd., electrical engineers, London and Leicester, to recover £500, the balance of an account for an installation of the electric light. Defendant had filed a counterclaim claiming damages for non-fulfilment of contract to have the installation completed by a certain date. Defendant was about to open new premises in Leeds and was desirous of having the building lighted electrically, and entered into a contract with plaintiffs to do the work. By the original contract, no actual time was fixed for completion of the work, but which was to be carried out in an expeditious and workmanlike manner. Defendant advertised the opening of the premises and engaged assistants, but on the date announced was unable to get any light, and thereby incurred considerable expense. The matters in dispute came before the Official Referee, and plaintiffs then took the point that although the assurance was given with the knowledge that it was intended to be acted upon, the promise was a mere naked one and was without consideration. The Official Referee came to the conclusion that the promise was not an absolute one, and that plaintiffs could not be made responsible for the delay which had occurred in connection with the fitting of the gas engine which was to supply the motive power. Defendant appealed to the Divisional Court, which held that the assurance was absolute and binding, but on the point that the promise was without consideration they thought there should be further arguments. The matter now came before their lordships on that point.

Mr. Justice DARLING thought that want of consideration being raised they had better hear the other side.

Mr. POLLOCK, for plaintiffs, said that the whole difficulty arose by the breakdown of the gas engine, which was not supplied by plaintiffs. His point, briefly, was, that there was no consideration coming to him which would make the contract binding.

Mr. Justice DARLING considered that the promise from defendant came distinctly within the rule which made it in the eyes of the Court of Equity a real binding contract made upon good consideration. Therefore there should be judgment for defendant with costs. The case would go back to the Official Referee to enable him to ascertain the amount of damages sustained by defendant.

Mr. POLLOCK asked for and obtained leave to appeal.

Binko v. Great Northern Railway Co.

In the Lord Mayor's Court (London) last week Mr. H. Binko sued the Great Northern Railway Co. to recover damages for injury caused to certain packages containing electrical appliances while in the care of the defendants in transit to Manchester. Mr. Lewis Glyn, for plaintiff, stated that on Feb. 17 his client sent to Manchester certain electric apparatus to be sold by auction. The goods were packed properly. When he heard that the goods arrived in a damaged condition, he at once informed defendants' agent, but the company refused to admit liability. The two cases contained three electrical sparking coils, sold in the trade at £12. 10s. each. In his letter to the auctioneer, he placed a nominal reserve price of £3. 10s. on each of the coils. Defendants' agents were informed that the cases contained electrical goods. For the defence it was contended that the cases were delivered in Manchester in the condition in which they were received by defendants, and that, if any damage was caused to the contents it was through negligent packing. Mr. Percy Huddleston, for defendants, said he inspected the cases in which the electrical apparatus were packed, and found they were good cases. He concluded that the coil had been damaged either before they were put into the cases or while being packed. He had sold similar instruments by auction at from £2. 15s. to £3. 10s. each, and that was considered a fair price. He put the instruments in the case up for sale, and had an offer of 30s. each. The jury found for plaintiff for £10. 10s. and costs.

Smoke Summonses.

At the West London Police Court on Saturday last, the Electric Traction Co. (Ltd.) were summoned by the Hammersmith Vestry for allowing quantities of black smoke to issue from two of their shafts in such a manner as to be a nuisance. Mr. Roskill (representing the Central London Railway) said that the Electric Traction Co. were the agents of that company. The shafts were used at the generating station of the new railway. Some evidence having been given, Mr. Roskill submitted that under the company's Act the defendants were not liable under the general law ; nor did the evidence prove that smoke was sent out in such quantities as to be a nuisance. The engineer in charge (Mr. Theodore Stevens) said that there had not been any negligence. The defendants had absolutely the best, latest and most approved plant for the conduct of their operations. It was true they were using cheap coal, the company not considering it necessary to incur the expense of purchasing Welsh coal for the experiments they were making. Mr. Roskill said that the two companies (the Central London Railway and the Electric Traction Co., Ltd.) were practically one, and with regard to the point he had raised as to the liability of the company, it was of such importance that he should ask for a case to be stated on the point. The magistrate said it was really a question of experiment and he thought a small fine only should be imposed. On this expression of opinion, Mr. Roskill did not press his application for a case to be stated. The company were ordered to pay £5. 5s. costs, and a prohibitive order against the company was granted.

Workmen's Compensation Act and the Assurance Companies.

At Woolwich (London) County Court recently, before Judge Addison, Q.C., Messrs. Thomas Carr and Son, contractors, Halifax, applied that payments of an award under the Workmen's Compensation Act to a painter named Folling should be determined, on the ground that he had not submitted himself to proper medical treatment, thus preventing his arm, which was injured, from properly healing. Mr. A. B. Bryceson represented Folling, and Mr. Willis the Credit Assurance and Guarantee Corporation, with which Messrs. Carr and Son were insured. Folling said that he had been to Guy's Hospital twice and had seen various doctors. Before the accident he earned £2 a week, and the assurance company had stopped the payment of 16s. per week for four weeks.

The judge remarked that it was a very high-handed proceeding and contempt of court. Execution should have been issued. It was a baseless application, and would be dismissed with costs.

PARLIAMENTARY INTELLIGENCE.

TELEGRAPHIC COMMUNICATION.

In the House of Commons on Tuesday,

Sir EDWARD SASSOON moved a resolution to the effect that it is desirable that an enquiry should be held into the commercial and strategic defects of Imperial telegraphic communication. The necessity for some such inquiry, he urged, was shown by the recent repeated failures that had occurred in the transmission of messages to and from the scene of our military operations in South Africa at a juncture when the efficiency of the lines and their freedom from interruption were matters of great importance to the nation. The associated telegraph companies, with the Eastern Co. at their head, had, he contended, neglected to supply public requirements at a period fraught with the greatest anxiety. He claimed that the subsidies granted to these companies were conditional upon telegraphic communication being in good working order and condition. Members of the House would remember that the East Coast of Africa cable was laid in consequence of the complaints made during the Zulu war. A period of 20 years had elapsed, and although the total subsidy and subventions to the associated companies amounted to £3,700,000, yet they had not duplicated their sections beyond the doubling of the Mozambique—Zanzibar cable. A legitimate commercial grievance was that the companies were earning a revenue largely in excess of what they had themselves declared to be an adequate return upon their capital and working expenses. He contended that the companies were bound to reduce their tariff. He called attention to the necessity that Parliament and Parliament alone should be the arbiter in the last resort as to what these tariffs should be and how the agreements entered into between Her Majesty's Government and the companies should be carried out. He might be told that the obvious remedy was for the State to buy up the cables, and he was prepared to argue the advantages of such a step when the time was ripe for this to be done. The companies had by degrees impregnably entrenched themselves behind mountains of conventions and joint-purse agreements, for which, as a business man, he admired their astuteness. He asked what was the most efficient means of altering this state of affairs, and urged that the inquiry which he proposed would give the solution to the problem. The situation of defencelessness to which great business communities were reduced was becoming a scandal, and an extraordinary part of the whole business was that one of the greatest sinners appeared to be the Indian Government, for their delegate at the International Telegraph Conference at Budapest in 1896 made strong efforts to obtain a reduction of the tariff to India, and while that attempt was defeated by the opposition of the Eastern Co. (on the admission of the Indian Government) their own cable from Kurachi to Bushire and Fao and their land lines from Bushire to Teheran had remained a stumbling block to the cheaper tariff advocated by their delegate at the Conference. As matters now stand, the Indian Government charged fourteen times as much from Fao to Kurachi as was charged by the Eastern Co. for identically the same length of submarine line—from England to Gibraltar. He found, on examination, that the Indian cable earned 85 per cent. of the whole sum earned by the Indian Telegraph Department, and that that department had been earning close upon 7 per cent., after paying over about £13,000 a year to the cable companies. The gross earnings of the Indian cable were £104,000 yearly. Assuming the gross value of such cables at £200 a mile—a very liberal estimate—a new line would cost about £240,000, so that the House would see that the cable earned no less than 50 per cent. annually. The charge to India remained 4s. per word, and to Australia—about double the distance—it was equally 4s. a word. This anomaly had wider-reaching consequences, inasmuch as the rates further east—to China and Japan—were maintained proportionately higher to the Indian rate. They knew that the Eastern Co. were content to receive only 1s. 2½d. or 1s. 4½d. for their share of messages passing through Bombay destined for Australia, so that they had, in the words of the Chancellor of the Exchequer, "a very considerable grievance." He urged that no reduction in the Indian rate would be at all satisfactory which did not reduce the charge to 1s. a word. He and those who were with him in this matter advocated joint guarantee by the Indian and the home Governments of one-third of any loss resulting from the lowering of the rate to 1s. a word. That was a matter which principally, though not exclusively, concerned the Indian Government. If the worst came and no augmentation of traffic followed, the utmost the British Treasury would be called upon to disburse would be about £30,000 on its half-share, and, curiously enough, a windfall of £28,000 a year, represented by the Red Sea annuities, would accrue to the Chancellor of the Exchequer in 1905. Then, as to the West African tariff. A message to Sierra Leone, to Lagos, or to the Gold Coast costs nearly 7s. a word, whereas a word to the Cape costs 4s., and a Frenchman was able to send a message to his West African possessions at 1s. 5d. a word. Whereas in France they could send a message to the furthest confines of Tunis and Algiers for ½d. a word, they in England had to pay no less than 1s. 9d. to cable to Egypt, or nearly 40 times as much. This brought him to the Pacific cable scheme. Although some of the signatory States to that project appeared to have been seduced from their allegiance, he fervently hoped that means would be contrived to prevent its collapsing. It had worked a truly chastening influence on the associated companies. The metamorphosis it had wrought had been miraculous, because, while they were asking £75,000 a year subsidy for the establishment of the Cape-Australian cable, since the birth of that scheme they had agreed to altogether waive that demand, accompanying that renunciation with a promise of lower rates. What was wanted in connection with this important subject was a State policy, far-seeing in its scope and embracing the comprehensive interests of the constituent portions of the Empire. He would humbly suggest that it should provide, among other things, in all future agreements with private contractors, the fixing of a scale of charges based upon the average earnings—say, for three years—and working on a sliding scale, and that no concessions either material or geographical should be granted to any system that diverged from or conflicted with the all-British route. It should also provide that no absorption of any new line by old companies should be permitted without the express sanction and concurrence of the State ; that the State should be able to assume ownership—and this was the point of cardinal importance —when such a step was dictated by the public interest ; that when a cable broke down for the best part of three months owing to avoidable causes some suitable penalty should be inflicted ; and, finally, that no exclusive privileges in restriction of competition, except when dictated by some imperious temporary necessity, should be granted. Another point was the terminal tax of 2d. a word, which, according to the International Telegraphic Convention, was leviable by the Treasury. This involved a sum of £90,000 a year. The House would see there were many points worthy the attention of a strong committee of business men and telegraph experts. No one could forget the eminent services rendered in the early days of cable enterprise by the late Sir John Pender, and his eminent successor Lord Tweeddale, but they held that those services by the parent company had already been requited, either in meal or in malt. It was time the public were considered. He concluded by moving the resolution standing in his name.

Sir C. DILKE said that this was a question in which the chambers of commerce and the trading classes were deeply interested. He agreed with the

Digitized by Google

terms of the resolution, but would prefer to treat it from a different standpoint. The House had heard the commercial side of the subject, but he would deal with the strategic side. Personally he wished to see us get the largest number of cables in different parts of the world, because he was persuaded that our superiority at sea would be most powerfully aided in time of war by the greater number of cables we could possess. Much progress had been made. His great object was to obtain various alternative routes to be used in time of war, and he firmly believed that an important national object could be attained without heavy cost to the country. Cables would undoubtedly be largely cut in time of war, but it was highly improbable that all of them would be cut, and if we had alternative routes the probability was that one or two cables would remain intact, and that we would thus have an immense advantage over our opponents. During the Cuban war the United States cut certain cables, and paid compensation in certain cases. Of course in our case the payment of compensation would be a small matter. He wished to insist on the importance of deep-sea landing of cables, and pointed out that while the landings on the Cornish coast were shallow, those on the west coast of Ireland were in deep water. This was a matter to which he thought the Government should give their attention, not only from a strategical, but from a commercial point of view. He was one of those who favoured the purchase of the cables by the State at their real value or price. At all events, the purchase question was one worthy of inquiry.

Mr. VICARY GIBBS said Sir E. Sassoon had complained of the associated cable companies that they did their work badly and were very inefficient in the time of war, and that their charges were excessive. As to exorbitant tariffs, it was impossible to have a uniform mileage rate to the West Coast of Africa. The charge was high because the amount of traffic was so small. As to the land rate across India being reduced to a 1s., by an agreement between the Indian Government and the telegraph companies the rate had been reduced from 4s. to 2s. 6d., and that new rate would, it was believed, show a substantial loss. Of that loss the Indian Government would bear one-third and the companies two-thirds. The companies had also made large reductions both to South Africa and to Australia, and these were to be followed by further reductions. About 12 months ago the companies offered the Post Office to reduce their rates to 2s. 6d. provided they earned a certain minimum profit. That proposal was a fair one. The companies had made reductions from 4s. 9d. to 4s. to South Africa since May 1, and from 5s. to 4s. to Australia since September last. With regard to the new cable route to Australia, the companies did not ask for a subsidy, but that they should have the right of communicating directly with the public as was the case in this country. If the Government ultimately had their own Pacific cable and still retained control over the companies' telegrams, obviously the interests of the companies' trade rivals would be in the Government's hands, and no one would send messages by the company's cables when they could send them by the Pacific route. It was therefore most important in the interests of the public that the demand of the company should be conceded, and it had been conceded by the Governments of South Australia, Western Australia, and Tasmania. The companies had done a great deal for the Empire in providing strategic cables. With regard to the desire of the Government to have a cable constructed from Ascension to Sierra Leone, it appeared that the cost of such a cable would be about £15,000, and it was estimated that the return on such an outlay should be £11,000. The companies had agreed to make that cable for a subsidy of £4,500 a year, although the traffic was practically nil. An inquiry into the relations of the Government with the cable companies might be detrimental to the interests of this country in regard to foreign nations. He had no interest whatever in these companies, except to see that justice was done, and to give the House an opportunity of considering both sides of this question.

Mr. S. BUXTON said they all agreed that the Eastern and associated companies had done a great deal for submarine communication and towards placing almost the whole of the submarine lines in English hands, but it should be remembered that they had not made a bad thing of it. The Foreign Office, Colonial Office, and other Government departments interested in submarine telegraphy should have some settled policy whether the cables should be State cables or commercial cables. Their interests conflicted, and some general agreement should be come to. It was never intended, when the companies were subsidised and given charters, that they should combine into a monopoly to the detriment of the public interest.

Mr. R. W. HANBURY (Secretary to the Treasury), said in reply: The honourable member who moved this resolution was chiefly interested in the subject of cheap telegraphs. The right honourable gentleman opposite who seconded was, on the contrary, more interested in the question of the strategic cables. There is, therefore, *prima facie* a little inconsistency between the mover and the seconder of the resolution, because while commercial cables, to which we must principally look for cheaper telegrams, depend upon tapping every available source of traffic, the chief strategic cables, of course, avoid to a very great extent, or in fact wholly, foreign countries, which to an ordinary cable provide a very large source of traffic, and at the same time avoid all English stations which are not of considerable importance and which are not easy of defence. That being so, I think there is a little inconsistency in the resolution itself. As a matter of fact, this great system of submarine cables, like most other things worth anything in this country, has grown up quite haphazard, and the result is we have a system which is partly strategic and partly commercial, and which some people say has, therefore, got the merits of neither. I hope I shall be able to show that only a very little is wanting to give us not only good strategic cables, but also cheap commercial cables. Still, I admit that at the present time we have not got either completely. I think the hon. member opposite did a good service in calling attention to the really great work which these companies have done, because, after all, here are great private companies which have built up a great system with which the system of no other country can for one moment compare. They have given us great links between ourselves and the colonies, between ourselves and our coaling stations; they have put us into a position that we are able to get the first news from all over the world, and surely for a great nation like ourselves, in time of war and in time of peace, in diplomacy and in commerce alike, to get, as we invariably do, the first news is a matter of the very greatest importance possible. These companies have given us such an effective service all over the world that it is now exciting the jealousy of foreign nations, and complaints are now arising both in France and in Germany that so completely British is this system that we are excluding all foreign nations from participation in its benefits, and, of course, great complaints have been raised as to the way in which in time of war at any rate we are able to censor their telegrams. Take the case of France. It is the fact that with the exception of her West Indian colonies and Tunis and Algeria, France everywhere depends for communication with her own colonies upon British cables alone. I say that a company which will put this country in a position of that kind is a company to which the country is very much indebted. I will go further and say that to a great extent these companies have given us advantages which we could not have possessed even if these cables had been in our own hands, because, owing to the fact that these are private companies, at nearly all their foreign stations at which their cables land they are allowed to have as their employés all British subjects. Everybody can see what a great advantage that is to this country, but it is an advantage which certainly would not be allowed to us if those cables were owned by the Government or the State. The hon. member opposite said a great deal about the tax-payer—that it was unfair that the tax-payer should not have some voice in settling the rates demanded by these companies. But after all the tax-payers have had very little whatever to do with building up the companies, or with building up the system. No doubt we have to give subsidies for strategic cables, but beyond that we have done nothing at all. Take the great route to India. Did the taxpayer contribute a single farthing? Take the cable to China: He has not contributed to that. Take the route to Australia. The Australian colonies, no doubt, contributed something, but the Imperial taxpayer has not given one halfpenny. Therefore, after all, the connection between the taxpayer and the companies is not a very close one. Then there was the complaint raised as to these companies not duplicating their lines. That was raised by the hon. member for Hythe. What is the position in regard to that? I think if the hon. member will consult the War Office or the Admiralty he will find that they do not encourage the duplication of cables—at any rate, cables running side by side; in the first place because it is much easier to destroy communication, and, in the second place, because it is much more advantageous to the War Office that the cables should run in different directions connecting different places rather than that the two should run side by side. My hon. friend complained of certain rates. I noticed that he made no general complaint as to rates, but he singled out particular portions of the cables. He omitted to mention what I think is an important fact, that everywhere—I believe without exception—wherever those cables run, the British Government not only has priority, but also sends messages at half rates. That, of course, is a considerable advantage. The comparison of submarine rates with low rates was absurd. Complaint was made of the interruption of these two cables. I believe, as a matter of fact, that on one side of Africa the cables are interrupted on an average for 60 days in the year, and on the other side for 40 days. This is due to the very uneven formation of the bottom and also to certain upheavals which are constantly taking place and injuring the cables. In regard to submarine cables themselves, it is interesting to see what is the actual force of these rates when worked out to the number of miles a message can be sent for a penny. I have been supplied with the following information: Taking the Atlantic cables, where, of course, I admit there is a great deal more competition than exists in the case of the Eastern cables and the associated companies, between London and New York you can send a message 268 miles for a penny at the current 1s. rate. You are able to send messages to Australia at exactly the same rate—that is to say, taking Sydney, you are able to send 259 miles for a penny at the rate of 4s. To Singapore at the present rate you can send 157 miles for a penny; Hong Kong, 150; the Cape, 140; and Bombay, 135; and it really points to the fact that the proper rate to India, judging by the rates of the Atlantic cables, is 2s. I was surprised to hear my hon. friend ask the Imperial Government to subsidise or to guarantee the cables. I understand that the hon. member has taken part in a deputation to the Chancellor of the Exchequer which repudiated any idea of the sort. What is the position? No doubt we have subsidised the Indian cables, but I utterly deny that it is our duty to provide low rates at the public cost for the companies to pay high dividends. At present it would be perfectly and entirely wrong for the Imperial Government to supply public funds in order to benefit one particular class and one particular section of the community.

Then, my hon. friend, he wanted us to reserve the right to buy up these companies. With regard to strategic cables, in certain instances we have reserved that right already. My hon. friend knows that in the case of the cable going to Singapore by Borneo to Hong Kong we have reserved that right, and I think we can buy it up at £300,000. There is a similar stipulation with regard to the cable running in Egypt between Suez and Suakim; that, I think, the Egyptian Government, with the consent of our own Government, can purchase at any time for £200,000. But what is the good of a right to buy purely commercial cables unless the Government is going to buy up cables generally, and run those cables as a commercial system? That, at any rate, is a step the Government have not taken yet, and I sincerely hope it will be a long time before they think of doing so. But, even if the Government were to do that, I hardly think it is a fair thing to do to the companies, because the companies lay these cables with the intention of making them commercial successes. Are we to say to these companies, "Oh, if the cables are a failure you can keep them on your hands, but if they are a success we have a right to purchase them?" If the Government did buy the cables we should lose the advan-

Digitized by Google

tages on foreign territory which the private companies at present possess. As to the question of competition—competition, it seems to me, is the remedy for this evil as it is for many others. One hon. member compared the existing cables with a company with regard to which he and I both had something to do, where a monopoly was claimed. But in this case there is no monopoly whatever claimed ; the cable companies do not for a moment contend that the Government is under any obligation whatever with regard to them, or has given them anything in the shape of a monopoly. We are under great obligations to these companies, and if they treat us fairly, we are bound to treat them fairly in return ; and it is only when they try to create artificial monopolies or charge unduly high rates that we could at all fairly enter into competition with them. The companies had in many cases reduced their rates considerably during the last nine years. In 1891 the rate to Hong Kong and Shanghai was 7s., in 1897 it was reduced to 5s. 6d. ; in 1891 the rate to Penang was 5s., it is now reduced to 4s. 6d. ; the rate to Singapore has been reduced from 5s. 9d. to 4s. 6d. ; to Japan from 10s. 8d. to 7s. 9d. ; to the Cape from 8s. 9d., in 1890, to 4s. at present. These are substantial reductions. My hon. friend complained of particular rates ; he complained especially of the rate to Egypt, the rate to West Africa, and the rate to India. Some curious illustrations of the kind of rates which these companies are expected to agree to have been given—the case of a halfpenny rate between France and Tunis and Algeria. I do not suppose that he himself expects that the companies are going to give us a halfpenny rate for distances of that sort. What is the fact? France deliberately treats Tunis and Algeria as being a part of France itself, and all these rates are treated as interior rates. Moreover, these are Government cables, and the whole traffic between France and Tunis and Algeria is carried on at an enormous loss to the French Government. My hon. friend does not expect either the British Government or these commercial companies to do their business at a loss like that, I am sure. Equally cogent reasons against adoption of the rates on the land lines from St. Petersburg to Vladivostok could be given. Then there is the case of the 1s. 5d. rate to St. Louis. He said, "It is perfectly monstrous that these cable companies should charge 6s. or 7s. to British Colonies in West Africa when it is possible for a Frenchman to send to his colonies at a cost of 1s. 5d. per word." What are the facts connected with the cable running between France and St. Louis? The French rate is a very low one, and when you get below a certain place two-thirds of the line belongs to the French Government and one-third to the French National Company, which I believe is really an English company. It is admitted that the service from Cadiz is carried on at a loss to the Government concerned, and it is further a fact that it is carried on at a great loss to the company which owns a third interest in the cable. It is a fact that in 1898 that company lost no less than £6,000.

Now, as to India. There is, first, the case of Egypt. This is not a monopoly, it is a privilege—that is to say, when a concession is asked for for a new line, the company has the right to say to the Egyptian Government, "Give us the first chance of making it." That privilege would entirely disappear if at any moment the line between Suez and Suakim was bought up by either Government at a cost of £200,000. As to my friend's idea that the company have any control over the Tripoli-Constantinople line, this is, the Company assure me, not the case. They have no more influence over that line than has my hon. friend himself. The Indian case is a wholly exceptional one. I do think that there the company tried to create an artificial monopoly, which was not in the public interest. I think the way in which they, in the first place, gained practical possession in 1887 of the Indo-European line, and then by a manœuvre, which was certainly ingenious, forced the Indian Government to come into the pool with them—I say it was very ingenious, but at any rate it does not put that company, so far as the rate to India is concerned, in a position to claim any very great consideration from the Government. The Indian rate was fixed at 4s. in 1886, and at 4s. it has remained ever since. Meanwhile, all the trans-Indian rates have been very largely reduced, and the result has been, no doubt, to block the cables on this side of India. Therefore, the question arises, even if the rates were reduced to India, would the carrying capacity of the existing cables be such as would be able to meet the increased traffic which would presumably follow? One hon. member said that if the companies could afford to charge cheap rates for a section of the line you have only to add the rates together and you would get a fair rate for the whole distance. But you cannot arrive at what is a fair through rate by merely adding interior rates together. The interior rates of a country are based upon a system both of short and long distances ; that is to say, a claim is made that we can afford to send a message for a halfpenny a word in England because a large number of those messages are short messages, but we could not undertake to send messages on a line from the south of England to the north of Scotland for the same price, because our calculations are not made on that basis. Exactly the same argument applies to the line to India. The result of the negotiations which have taken place between the Indian Government—which I think has made a very good fight with the cable company—has been already given by Mr. Vicary Gibbs. I understand it is practically arranged that there should be at once a reduction to 2s. 6d., and if the 2s. 6d. rate brings in a certain number of messages that rate will shortly be reduced to 2s.

Just one other word as to strategic cables. There again I think we owe a great debt to these companies. No doubt all British cables are to a great extent a new and recent idea, but very much has already been done by the companies to meet the demands for strategic cables. It is interesting to note that nearly all their existing cables run along the main routes of trade, and therefore are more easily defended by our fleet. Of course we have got a British staff in nearly every foreign station, and even where those lines do touch at foreign stations in time of war they could be easily cut, and give us a complete all-British cable even in those cases where cables are not at present all-British. What has been done recently, and within the last few years? We have got a new line complete from the Cape to St. Helena and Ascension all-British ; we have had a new line from Colombo to Gibraltar instead of touching at Lisbon ; we have got a new line to Singapore and Hong Kong ; we have got a new line from Bermuda to Jamaica ; and we have, in fact, got all-British lines to Malta, Cyprus, Egypt, Aden, India, Ceylon, the Straits, Hong Kong, Zanzibar, British South Africa, Canada, Bermuda, and Jamaica. We have not got them at the present moment to the Cape, but we shall get them by this new line passing from Durban to Mauritius, and so on up to the north. We have not got them to West Africa at present, but we shall get them when that line is completed ; we have not got them to Australia at the present moment, but we shall get them when the new line is completed. And though, undoubtedly, we have not got them to the West Indies, with the exception of Jamaica there is only one important point there, St. Lucia, which is not in connection with England by an all-British cable, and that is being considered by the Government, Not only is it the case that we shall get these all-British communications, but instead of depending upon single cables—certainly, if we get this Pacific cable and this line from Durban to Australia—we shall not only get these all-British cables duplicated, but probably triplicated and quadrupled. That is a very important consideration indeed. Then, of course, the last step which has been taken is the line running to St. Vincent and on to Ascension, St. Helena, and the Cape. I have shown that rates have been reduced in a great many instances, and steps are being taken to give us strategic cables practically all over the world. This motion for an inquiry is framed in very general terms, and I hope the inquiry by the Government will satisfy the hon. member. I would ask my hon. friend not to press for a public inquiry. These cables are largely strategic. Is it wise that a committee should go publicly into all these questions of strategic cables? There is also another consideration. I have stated the enormous advantages which this country possesses over other nations in the extent of our cables, and shown the great degree to which foreign nations depend upon British communications. Is it wise to parade this position before foreign nations? Is it not better, if we can, to continue to enjoy the opportunities which we still have, and not, by parading our present advantages, induce other nations to greater jealousy? I can assure the hon. member that if he leaves this matter in the hands of the Government, he leaves it in the hands of men who take the greatest interest in the subject and who are determined to meet not only the views in the direction of cheap telegrams, but also the views of the right hon. baronet with regard to strategic cables. These submarine lines are the true nerves of the empire ; they are the nerves by which all these colonies are brought into simultaneous action with ourselves ; they transmit to them, almost in a moment of time, those innumerable and unnumbered sympathies, those common joys and common sorrows which are shared between the Mother Country, the mother-land, and her many and distant daughters.

Sir E. SASSOON : This is the first time in the history of the House since the invention of telegraphy that any full discussion has taken place on the subject. My right hon. friend intimated that we should have an inquiry by the Government, and I must reluctantly accept this proposal. Did I understand him to offer a select committee?

Mr. HANBURY : No! I said the resolution asked for an inquiry, that we were perfectly willing to make that inquiry, that that inquiry could not be by a committee of the House, but by the Government in the different departments.

Sir E. SASSOON : Under those conditions no member of this House would have a right to ask for papers or information or to go into any matters connected with the inquiry. That would be highly unsatisfactory, and therefore I think I must go to a division.

Mr. A. J. BALFOUR : The hon. member appeared to be dissatisfied with the suggestion of the Secretary to the Treasury that the inquiry should be by departmental committee or some other machinery than that provided by the ordinary Parliamentary committee. He says that an inquiry from which members of this House are excluded would be highly unsatisfactory. But my hon friend must recollect that we have not merely to consider commercial interests in this matter, but also strategic interests. I cannot imagine anything which would be less expedient from a public point of view than an inquiry by a committee of this House into strategic considerations. Everything which he asks for in his resolution we are prepared to grant, but we cannot agree to a public inquiry, nor is that contained in the terms of his resolution.

Sir E. SASSOON : On patriotic grounds, relying on the assurance of my right hon. friend, I beg leave to withdraw the resolution.

The resolution was by leave withdrawn.

COUNTY OF DURHAM AND TYNESIDE ELECTRIC POWER BILLS.

On Wednesday last week, before the Special Committee of the House of Commons (presided over by Sir J. Kitson) to consider the Electric Power Bills now before Parliament, Mr. J. A. JECKELL, electrical engineer to the Corporation of South Shields, stated that he was appointed to the position in 1893, and had advised the Corporation with regard to the system of supply inaugurated under their Electric Lighting order. The generating station had been erected on a site on the river in the very centre of the works of the town, where there was a good supply of water and a cheap supply of coal. Asked why he advised the adoption of the single-phase system, he said that when the works were laid out there were three systems in use. One was the low-tension continuous current system, the second the high-tension continuous current, and the third single-phase alternating current. At that time the Board of Trade had not raised the pressure for low continuous distribution. They eventually doubled it, and thereby made it a good distributing current. To have supplied South Shields by a high-tension direct current system would have cost twice as much capital outlay as the single-phase alternating current system. The multiphase direct

Digitized by Google

current system was then practically unknown in England. The ordinary periodicity of the alternating single-phase current was 100 periods, but this was unsuitable for motors, and the Corporation, therefore, reduced the periodicity to 50 periods. If a demand for power arose in the district that would increase the load factor, which was not very good now. South Shields had adopted the Brighton system of charging for current, which was absolutely equitable to all consumers irrespective of size. The Corporation was supplying its consumers profitably and well. Its undertaking was of considerable market value, and if any company, such as the Tyneside Co., purchased it would certainly be willing to give a much larger sum than it had cost the Corporation to instal it. At present 1,450 E.H.P. was available at the station, and by the end of August they would have 2,500 H.P. The capital cost of the present works, land, and distributing system was £60 per H.P. The distributing system alone had up to the present time cost about £30 per H.P.

Col. LONG: What is the lowest price at which you can supply electricity?—It depends entirely on the load factor.

Take an ordinary factory, working 10 hours a day, and doing an ordinary, fairly level amount of business?—Well, somewhere between 1½d. and ¾d. per unit.

Would it, then, in your opinion, be a hardship if we said that for power purposes the maximum they were allowed to charge for their first 100 hours must be 2d. under the sliding scale?—It rather depends on what the second 100 hours are going to be. I do not think it would be a hardship to fix 2d., because the lower the price the sooner people would take it up, and they would be recouped in that way.

As a matter of fact, in order to sell you must reduce the price?—Yes.

Mr. HANS HAMILTON addressed the Committee for the South Shields Corporation, and said that if the Tyneside Co. were willing to supply the Corporation in bulk without competing with them they would be welcomed, but the Corporation thought that competition in distribution would be most unfair, and that it was entirely unnecessary that fresh mains should be laid under the streets of the town.

Speaking for the Corporation of Jarrow, Mr. HANS HAMILTON said his clients were willing to have the electric supply placed in the hands of the County of Durham Electric Power Supply Co. They had satisfied themselves that the Company would be able to meet all demands in the present and future in Jarrow for all purposes, and that it was financially strong enough to carry out its undertaking. They objected, however, to competition in distribution between the two companies being permitted in their district.

Mr. MOON, for the Durham Electrical Power Distribution Co., said the Company was in a position, under the terms of provisional orders, to supply the municipal borough of Gateshead and Jarrow and the urban district of Wickham with electricity. It wished to be in a position to obtain electricity in bulk from the County of Durham Electric Power Supply Co., and it objected to the Tyneside Co. being allowed to compete in distribution with the County of Durham Co. even with the consent of the local authorities.

Mr. J. D. FITZGERALD, Q.C., for the Walker and Wallsend Gas Co., which under its Act of last year has power to supply the electric light, contended that the company could supply electricity at as low a rate as the Tyneside Co. His company was, he said, spending a large sum in laying down plant, and it would be a very wrong thing for Parliament, after passing the Act of last year, to allow another company to compete with it.

Mr. C. MERZ, who has advised the Walker and Wallsend Gas Co. with respect to their electrical undertaking, said he thought the amount of power likely to be required in the district, even for large works, had been exaggerated by the promoters of the Tyneside bill. He did not think that competition between the Tyneside Co. and the Walker and Wallsend Co. would be beneficial in any way. If the Tyneside Co. wished to supply the whole of the district contemplated in the bill he was of opinion that they would eventually have to build at least three generating stations. It would not be economical to transmit energy throughout the district from a single generating station, as loss in transmission would more than counterbalance economy in generation. The Walker and Wallsend Co. had provided an exceptionally good sliding scale for the benefit of the consumer, and under no circumstances could the company divide a bigger dividend than 10 or 11 per cent. The company had laid down cables and placed contracts to the extent of £30,000, and was in course of erecting a station in which some 5,000 H.P. would be provided. They looked forward to starting a supply in August next, and had made contracts to that effect. Special attention had been paid to the provision of a supply for manufacturers, and for the benefit of large manufacturers polyphase motors were being provided. The company had offered manufacturers a maximum rate of 4d. for the first hour per day throughout the half-year, and of 1d. afterwards. They had, however, made it known that they would charge the lowest price they possibly could, and they hoped eventually to bring down the price to 1d. per unit for the ordinary manufacturer. The company had made a working arrangement with the Newcastle Electric Supply Co., and the two companies in combination would shortly be able to supply not only Walker and Wallsend but a large part of Newcastle and the whole of Willington, Long Benton, and Gosforth. He contended that the prices of the Walker and Wallsend Gas Co. compared favourably with those of the Tyneside Co., and that while the Tyneside Co. would not be in a position to supply for at least two years, the Walker and Wallsend Co. could supply at once.

Mr. S. HUNTER, manager and director of the North-Eastern Marine Engineering Co., Wallsend, employing some 2,000 men, said the company had an agreement with the Walker and Wallsend Gas Co. for a supply of electricity at a price which he considered to be reasonable and fair.

Mr. S. T. HARRISON, chairman of the Wallsend District Council, said the Council last year supported the electric supply proposals then made by the Walker and Wallsend Gas Co. The Council had considered the question of competition between the Tyneside and Walker and Wallsend companies, and were of opinion that, in view of the arrangement come to last year and embodied in the Gas Co.'s Act, it would be inadvisable that another company should be allowed to come into the district. The Council had made special terms with the Gas Co., and they thought it reasonable that that company should have time to carry out their proposals. That was practically the unanimous feeling of the Council.

Mr. WILSON CARR, consulting electrical engineer, Newcastle-on-Tyne said he was electrical adviser to the North-Eastern Marine Engineering Co. which had made arrangements to receive 700 E.H.P. from the Walker and Wallsend Co. He considered that the system adopted by the last-named company was one by which electricity could be economically generated.

Mr. CHARLES HOPKINSON (Messrs. Hopkinson and Talbot), speaking to the point of compactness of area in the supply of electricity, said the district which the Walker and Wallsend Gas Co. and the Newcastle Electric Supply Co. proposed to supply was an excellent one for the purpose.

Mr. C. MERZ, recalled for the Newcastle Electric Supply Co., said the present generating station of that company being unsuitable for their extended undertaking, they proposed to acquire a new site on the river side in Wallsend. The Tyneside Co. also proposed to acquire the same site, which was the only one available near Newcastle for generating electricity at a cheap rate. The Newcastle Electric Supply Co., in the bill now before Parliament, had scheduled two other sites besides that at Wallsend. He was not aware that the owners of the Wallsend site had agreed to sell it to the Tyneside Co.

Dr. J. T. MERZ, vice-chairman of the Newcastle-on-Tyne Electric Supply Co., said the capital of the company was now £300,000, of which £200,000 had been allotted. In 1890 the company came to an agreement with the Newcastle District Electric Lighting Co., with the knowledge of the Corporation of Newcastle, that each company should confine its operations to certain districts in the city. He strongly objected to the bill of the Tyneside Co., his own company being able and willing to meet any demand for the supply of electricity in its own district. The Newcastle Electric Supply Co. had been in negotiation for the Wallsend site since February, 1898, and the site was scheduled before it was known that the Tyneside Co. were going to schedule it. An agreement had been made with the Walker and Wallsend Gas Co. to supply them with electricity in bulk, the gas company to be their own distributors.

Mr. J. S. WATSON, engineer of the Newcastle-on-Tyne Electric Supply Co., said they had been supplying electric energy for the last 12 years. Till two years ago the system in use was the alternating current. As it was found that some other system was needed, he visited all the electric supply works in this country and in Switzerland, and, as a result of the recommendations he afterwards made, it was decided to adopt the continuous current system. The company were prepared to supply manufacturers with the whole of their electrical equipment without initial cost to them. They were now laying cables capable of dealing with any amount of power required in the city. In order to meet the demand for power it was proposed to charge a rate which he believed was unprecedent at the present time—namely, 4d. per unit for the first hour's use per day and 1d. for the second and subsequent hours. These were the maximum prices, and all manufacturers understood that the company hoped to supply them at a lower price. The charge for lighting would be almost equally low—namely, 4½d. for the first two hours and 1d. after. These rates were not to be found in the company's provisional order, but they had offered to make contracts to supply at those rates. They had not sent out a circular notifying their intention of charging at such rates, but had negotiated with manufacturers, and had actually made contracts on that basis. The rates had not been lowered merely to meet the competition of the Tyneside Co., arrangements having been made before the Tyneside bill appeared.

Mr. ROBT. HAMMOND stated that he was for years the pioneer of the system of one large generating station for the supply of a large district, and was consulting engineer to about 28 local authorities. He had prepared an analysis of the Board of Trade returns respecting the cost of production in all the leading electric works in the country. The analysis showed that the load factors were in most cases low. In the case of Leeds, for instance, whose works he laid down himself, the load factor was little more than 10 per cent, and the cost of production was 1·29 of a penny per unit. No load factor of 25 per cent. existed in this country. He had compared the prices proposed to be charged by the Newcastle Electric Supply Co. in connection with the Gas Co., and those proposed by the Tyneside Co. They seemed to be reasonable prices. The area of the Newcastle Electric Supply Co. was one in which he thought that electricity could be as cheaply produced as it could be in the larger area proposed by the Tyneside Co. There was a point in the enlargement of works at which the limit of economy was reached. He put the figure of economy at between 5,000 and 10,000 kilowatts. The district mapped out by the Newcastle Electric Supply Co. was an extremely favourable one for an economical supply.

Prof. W. E. AYRTON stated that, in his opinion, the charges of the Newcastle Electric Supply Co. compared most favourably with the proposed charges of the Tyneside Co. He did not think the area mapped out by the Tyneside promoters north of the Tyne could be economically supplied from one station.

The Committee then adjourned till Wednesday.

THE ELECTRIC POWER BILLS.

At the meeting of the Committee on Wednesday, when proceedings on the Electric Power bills were resumed, Sir J. Kitson presiding, after Mr. Balfour Browne, Q.C., had addressed the Committee on behalf of the County of Durham Electric Power Supply Co.,

The CHAIRMAN said he wished to state, for the Committee, that the value of electrical energy as a means of power had been amply demonstrated and its importance to industries in this country was admitted

Digitized by Google

The Committee felt that it was to the public advantage to facilitate measures which would ensure the general supply of electrical power to all consumers who might seek to avail themselves of the economy and efficiency offered in the service of these sources of the application of the power. The Committee, therefore, did not require the constant repetition of scientific evidence to prove that which had already been proved to their satisfaction.

LANCASHIRE ELECTRIC POWER CO.'S BILL.

Mr. WORSLEY TAYLOR, Q.C., then opened the case of the Lancashire Electric Power Co. He said their bill was one to authorise them to supply electric power over a large area lying south of the Ribble. The company was to have a capital of £3,000,000, with borrowing powers to the extent of an additional £1,000,000. Four generating stations were to be constructed—one near St. Helens, one near Wigan, one at Little Lever, near Bolton, and one to the south of Eccles, near Manchester. The only opposition came from the local authorities, and the question was one really of wayleaves. The company sought to supply in bulk those who were already authorised by Board of Trade licence, or provisional order, or special act to supply electricity. It would thus be seen that it was not proposed to compete either directly or indirectly with any of the local bodies. They did not propose, as was proposed in the Durham and Tyneside bills, to supply individual customers directly ; they simply asked to be allowed to be the agents or servants of those who had already had power to supply on their own behalf. Thus the powers asked for in this bill were much more limited than those asked for in the other electric power bills. In the proposed area of supply there was a population of 3,000,000, and the industries carried on were more varied than in any other part of the United Kingdom. There were 84 urban districts in the county, and of these 65 did not oppose the bill. There were also 12 rural districts, and not one of them opposed it. Manchester Corporation and a number of other corporations, however, did oppose.

Mr. F. E. GRIPPER, electrical engineer, managing director of Edmundson's Electricity Corporation, and one of the promoters of the bill, said he regarded the scheme as a very good one. Electricity had never been generated on anything like the scale on which the company proposed to generate it. He thought that, with the exception of Niagara, there was no place where electric power could be generated as cheaply as it could be on a large scale in Lancashire. Four generating stations were proposed so as to obviate the necessity of conveying the power to too great distances. The Aspull station, near Wigan, would be so situated that it would not be necessary to handle the coal at all. The coal would be sent by mechanical means straight from the pits to the generating station. There was also a canal and a railway running close to the station. The same remarks applied to the St. Helens and Little Lever stations. There were 129 separate local authorities in the proposed area of supply and of these 16 had electric works in operation, and there were also three small private electric stations. The total output of the whole of the existing electric stations in the area was last year about 15,000 kw. The company proposed to design each of its stations for producing 15,000 kw. The object of the bill was more especially to supply the smaller local authorities, and it was only proposed to supply in bulk to companies or local authorities authorised to supply in their turn. The only compulsory power was practically that of laying down mains in order to get through one district into another. A mains voltage of 10,000 was proposed, and that would be transformed down so as to suit the requirements of the different customers. The whole of the four generating stations were not to be erected at once. In the first instance only one would be put up. The estimated cost of such a station was £555,000, including the cost of 180 miles of mains, each main being sufficient to carry about 1,000 H.P. Assuming that they would get a load-factor of 25 per cent., he estimated that at a station with a capacity of 12,500 kw. the cost of generation and distribution to the consumer would be 0·7 of a penny per unit. He estimated that the receipts would be £142,500 per annum, and the profit £62,000 from the one station. The company hoped to be able to supply at an average price of 1·25 of a penny per unit.

Yesterday (Thursday) Mr. GRIPPER was cross-examined by Mr. Freeman, Q.C., on behalf of Liverpool Corporation, and stated that under the bill the promoters would be obliged to supply all local authorities who asked for electric power, but they would be unable to supply individual consumers unless the local authorities gave their consent. Public bodies and companies who received a supply would have to guarantee to take, for seven years, an amount of energy equivalent to 20 per cent. of the cost of laying the mains. In putting down the mains the company would have to select a line approved by the local authorities, but if they objected to the decision of the local authorities they would have an appeal to the Board of Trade.

The committee then adjourned.

ELECTRIC LIGHTING IN DUBLIN.

A peculiar three-cornered electrical contest is in progress before a Committee of the House of Commons, consisting of Mr. A. H. Brown (chairman), Mr. Arthur Moore (Londonderry), Mr. Trevelyan, and Mr. Rutherford. Under the provisions of what is called the Dublin Electric Lighting Bill, a company, composed of some of the leading ratepayers and electrical power users in Dublin, ask to be incorporated, with a capital of half a million, for the purpose of establishing a generating station and other electrical plant on the banks of the city, in order to supply electric light to the city, a business which has hitherto been in the hands of the Corporation.

Mr. BALFOUR BROWNE, Q.C., in opening the case said the object of the bill was to incorporate a company, and to empower them to supply electricity in the city of Dublin and the urban districts of New Kilmarnham, Drumcondra, Clonliffe, Glasnevin, and Clontarf. The bill was promoted by certain very large ratepayers in Dublin who were tired of the continued inability of the Corporation to supply them with electricity for the purpose of introducing competition, which was very badly required. The history of electric lighting in Dublin was a record of failure. The Corporation had expended £90,000 on their electrical enterprise, and instead of a profit they had an income of only £10,704, and a net revenue of £1,424 with which to meet the whole of the interest and sinking fund upon the £90,000. They first of all accepted the tender of the Electrical Engineering Co. of Ireland for the generating station which was £30,714, and then they sublet the contract to Mr. R. Hammond with the result that the capital expenditure on the generating station, instead of being £30,000, came close up to £85,000. Their maximum charge being 7d. per unit, the result was that people would not take their electricity, and at the present time they had only 350 customers. The cables broke down in 1896, and the mains had to be relaid at a cost of £30,000. The site of the generating station was one of the most unsuitabe that could be chosen ; it was in the heart of the city, and the noise and vibration and smoke and other nuisances arising from it were complained of by the neighbours ; they had no facilities for getting water, and they had to cart their coal in and their ashes out. It was no wonder that with their large capital expenditure and their small clientele the Corporation were unable to give a satisfactory supply and in these circumstances a number of manufacturers in the city had installed electricity for themselves. The local authority having thus grossly failed in their duty to the promoters of the bill asked leave to come in and compete. Sir Francis Marindin had laid it down, "That in the abstract, competition is desirable, as tending to keep down the price and to cause the manufacture and supply of electricity to be carried on with all the attention and energy which it is possible to devote to it." That was the promoters' case. They wanted to supply electricity to reduce the prohibitive price of the Corporation and to ensure that the supply and manufacture should be carried on with proper attention and energy. The Dublin United Tramways Co., which had a very large electrical station for the purpose of operating their tramways, some years ago offered to supply the Corporation with electricity at a comparatively cheap price, and quite recently the same company had again offered the Corporation electricity at a price much lower than that at which the Corporation were supplying to the people of Dublin. Both these offers were declined. Apparently, therefore, the object of the Corporation was to keep their dead hand down and to prevent any one else from supplying elertricity. These were the circumstances in which the bill was promoted, and he would ask the conference, after hearing the evidence, to say that if ever there was a place in which a Corporation had failed to carry out their duty in the matter of electrical supply, it was Dublin.

Mr. WILLIAM MURPHY, chairman of the Dublin United Tramways Co., one of the promoters of the bill, and a director of one of the largest drapery establishments in Dublin, disclaimed the suggestion that there was any connection between the Tramways Co. and the promoting company, which was composed of some of the largest ratepayers and users of electricity in Dublin. He was also a director of the late Electric Lighting and Tramways Co. The present price charged for electric current by the Corporation of Dublin was between 6d. and 7d. per unit, compared with 4½d. to be charged by the new company, who estimated to make a profit. The charge for current at Cork was rather under 3d. per unit. Current for motive power at Cork was supplied at a still lower price compared with 6d. at Dublin.

Questioned by Mr. MOORE, a member of the committee, Mr. MURPHY said that if the Corporation would withdraw their prohibition against co-operation between the new company and the tramways company he believed it would be possible to supply at a penny less than the rates now charged. He could not, however, imagine the Corporation assenting to any arrangement which would leave their electric plant on their hands, but if the new company took over the existing plant and generating station of the Corporation probably electricity could be supplied at 4d. per unit. The Dublin United Tramways Co., being in a position to supply electricity in bulk cheaper than it could be supplied by the Corporation, had offered on two occasions to either take over the Electric Lighting Order of the Corporation or to supply them with electricity in bulk at a cheap rate, but both those offers were refused. The terms on which the Tramway Company were prepared to supply electricity were, for a consumption of 650,000 units, 2½d. per unit ; 1,300,000 units, 2¼d. per unit ; 2,600,000 units, 1⅞d. per unit ; as compared with a cost under Mr. Hammond's scheme, including loss on transformation, of 650,000 units, 4·55d. per unit ; 1,300,000 units, 3·15d. per unit ; 2,600,000 units, 2·45d. per unit. Under this proposal the Corporation were to retain the entire monopoly and control of the electric lighting.

WITNESS was cross-examined at length by Mr Burke, Q.C., with a view of proving identity between the promoting syndicate and the Dublin United Tramways Co., in whose Act there is a provision "That nothing in this Act shall empower the company to use or supply electrical power for any purpose whatsoever other than lighting and moving the carriages used on the tramways, and lighting the premises of the company, and for lighting the standards and posts for their own use."

Mr. C. W. HEALY, another promoter, confirmed that there was no connection between the proposed company and the Tramways Co., and explained that on the strength of the Corporation undertaking to light his printing works with electricity he did away with all his gas lamps and brackets, which he had to reinstate in consequence of the failure of the electric light, although his works were only three or four minutes walk from the Corporation's generating station. Whilst the gas lamps were being replaced he had to use oil lamps. If he could have got electric current for the purpose he would have driven all his machinery by electric power, but the current produced by the Corporation was not suitable and

Digitized by Google

consequently he used a large gas engine. There was, he said, a strong feeling amongst the shopkeepers and residents in Dublin in favour of having an independent supply of electric lighting in consequence of the dissatisfaction with the existing system, the prohibitive charges, and the inability of the Corporation to supply electricity.

Mr. HAMPTON SHAW, engineer for the township of Kilmainham, spoke as to the high charges for gas in that place, both for public and private lighting, and as to the demand for the supply of electricity in that district.

Mr. ARTHUR HANDLEY (Messrs. Handley and Shanks) said there were 270 subscribers to the Corporation supply, and the capacity of the present generating station was about 1,000 kw., equivalent to 1,500 H.P. for private lighting. There were also in Dublin about 70 private plants, with a capacity equivalent to 2,380 H.P. Even the new scheme of the Corporation did not provide for motive power, and it would certainly be of advantage to get competition.

Mr. ARTHUR EDWARD PORTE said that whereas in Cork, with a population of 80,000 they had 35,000 8 c.p. lamps actually burning at one time, in Dublin with a population of 250,000 they only had 27,000 lamps all told. In Dublin, again, there were no motors, while in Cork they had approximately 400 H.P. running daily. As a contractor he calculated that if they had had a similar amount of motive power in Dublin it would have meant £4,000 more into his firm's business. Under the rules of the Corporation it was practically impossible to have motors, as people were limited to a starting current which was of no use.

Mr. H. F. PARSHALL, consulting engineer to the Dublin United Tramways Co., said he had considered and worked out a proper system under the proposed scheme for the distribution of 2,000,000, 3,000,000, or even 5,000,000 units on the direct-current system. The sites for the generating stations were well chosen, and he believed the company would be able to supply electricity at a comparatively cheap rate. With a centrally-located station distributing electricity on a continuous-current system they would certainly be able to get 15 or 20 per cent. better efficiency, which was a most important matter where the cost of coal was very high. The main object was to get such a system of transmission and distribution as to obtain the highest efficiency with the least possible loss of energy. That was what the proposed system secured. If it was fit and proper to distribute 6,000,000 units for traction purposes, in this way it must be equally so for lighting purposes, because the losses in transmission of energy were identical. It was hoped under the scheme before the committee to combine with a lighting plant a supply of energy for power. The system which he desired to introduce was the best system for the distribution of power, because it was a demonstrated fact beyond dispute that continuous-current motors had energy factor unity in a higher degree than alternating-current motors. Electricity for power must necessarily be sold at a low rate because there were now in Dublin 3,000 H.P. gas engines, and the Gas Co. were in a position to supply power at a low rate. Such a price as 7d. per unit would be absolutely prohibitory and render it almost impossible to use electricity for power purposes in manufactories. Judging from his experience in the case of Cork he calculated that Dublin should consume from 2,000,000 to 3,000,000 units per annum, and that the receipts should amount to between £40,000 and £50,000. According to an official return the Corporation sold only 500,000 last year, and that would be more than doubled in twelve months if the people had a proper supply. After working the thing out carefully he came to the conclusion than an average price of between 4d. and 4½d. per unit would make the lighting remunerative, and that as far as power goes 2d. would be the outside figure. At these prices he calculated that the yield to the company would be £58,200, which, after deducting £15,000 for the cost of generation, would leave a net figure of £43,000. The current now supplied at the Corporation works was an 83 cycles 25-volt alternating current, and he proposed to supply a continuous current of 440 volts.

Mr. BALFOUR BROWNE, Q.C.: We know that you can get motors worked by alternating current, but not nearly so conveniently as by a continuous current?

WITNESS: Alternating current may be made to work motors physically satisfactorily, but I stand ready to prove by incontestible evidence that no alternating current motor can be shown to be as efficient as a continuous-current motor. Another point that I should like to bring out is that a continuous-current motor has energy factor unity, whereas in the case of an alternating-current motor no more than 90 per cent. of the current represents energy, so that to get the same result in your transmission and distribution system, which is of the utmost importance, the alternating current motor is at a distinct disadvantage.

Do you find, from your experience, that in many cases companies do their duty by the public in this respect just as well as corporations?—I think you may fairly say that companies can do better than corporations, for this reason: It is not one corporation in a dozen that can secure the services of a very high-grade man, for the simple reason that if he is a good man technically, he has to be a good deal of a politician in order to get anything done in a fit and proper way. That is a combination which is rarely to be found. The canny Scot, I think, has succeeded admirably in accomplishing this; but outside Scotland I am not sure that I have ever seen it accomplished.

Cross-examined by Mr. PEMBROKE STEPHENS, Q.C.: May I take it from you, as consulting engineer, to the Dublin United Tramways Co. that the works of the company are or are not adapted for electric lighting as distinguished from electric power?—The machinery could with some modification be used for electric lighting, but so far as distribution is concerned we could do nothing. The generators that we use are compounded for a particular drop in our mains. By cutting the compound-wound coils out, and getting the field-magnets rewound, and putting in a new switchboard, we could distribute if we had a proper system of mains.

Mr. PEMBER, Q.C., having addressed the committee on behalf of the Corporation of Dublin in opposition of the bill,

Mr. ROBERT HAMMOND was examined by Mr. Bushe, Q.C. He said the scheme of the Corporation, for which the estimate was £254,000, would cover the entire area of Dublin. He denied that the ex-mural generating station was a blot on the scheme, and asserted that in practice it would be found to work better than the low-pressure scheme advocated by the other side. He had just been through Europe, and he found that the idea of ex-mural sites for generating stations was becoming universal. The promoting syndicate proposed to use a continuous current, which had hitherto had the monopoly of the supply of motive power. On the other hand, he proposed in the case of the Corporation a current quite suitable for motive power, and one which was being used very largely inded for motive power, known as the three-phase alternating In connection with his Dublin scheme, he recommended a price of 4½d. per unit for private lighting and 2d. for public lighting, or an average of about 3½d.

The Right Hon. JOSEPH MEADE, Chairman of the Electric Lighting Committee of the Dublin Corporation, examined by Mr. J. D. Fitzgerald, Q.C., said as soon as the Corporation knew that the scheme now before the committee was fairly under way they consulted Prof. Kennedy, and arranged with him in the first instance to carry out the scheme, for which they took power to borrow £254,000. Prof. Kennedy, however, being under arrangement with the London County Council to go to America for them, Mr. Hammond was retained, and he prepared a scheme of which the Local Government Board approved, and sanctioned the expenditure of £254,000.

Mr. MARK RUDDLE, superintendent of electric lighting to the Dublin Corporation, explained the working of the present system.

Prof. SILVANUS P. THOMPSON, examined by Mr. Burke, Q.C., said that for motor purposes the three-phase alternating energy was more suitable than any other form of electric current. The scheme proposed by Mr. Hammond would supply motors adequateiy, and there was no foundation for the suggestion that a three-phase alternating scheme was inapplicable to motors. He also approved of the system of having the generating station outside the area of supply especially, in the case of large towns and cities. It was not economical to have the generating station in the centre of the area, and lighting stations ought to be few in number. In all these respects the Pigeon House Fort complied with modern theory.

Mr. George Pearson, of Bristol, Mr. Reginald Wigram, of Leeds, and Mr. Robert Styning, of Sheffield, expressed their preference to having electric lighting in the hands of corporations rather than of private companies.

Major PHILIP CARDEW (Messrs. Preece and Cardew), approved of the site selected by the Corporation of Dublin for a generating station outside the city. He did not approve of competition such as that sought to be set up by the promoting company, which he thought would involve the laying down of unnecessary mains.

Sir THOMAS PILE (Lord Mayor of Dublin) said they had formed a very firm determination to keep the lighting of the city in their own hands, and they meant to go on with the Order which they had obtained, and to spend the money which they were authorised to spend in extending and improving their system.

Mr. PEMBROKE STEPHENS, Q.C., addressed the Committee in the interests of the Alliance and Dublin Consumers' Gas Co., in opposition to the bill.

Mr. GORDON, Q.C., having summed up the case for the promoters,

The committee deliberated for some time in private. Ultimately the Chairman announced that the committee had decided to allow the bill to proceed on two conditions: (1) That the maximum price to be charged by the compeny should be reduced from 6d. to 5d. per unit; and (2) that a clause should be inserted in the bill enabling the Corporation to buy out the company if they should find it desirable hereafter to do so.

The inquiry lasted five days.

MANCHESTER AND LIVERPOOL ELECTRIC EXPRESS RAILWAY.

The consideration of the bill of the Manchester and Liverpool Electric Express Railway Company was resumed on Friday last by Sir John Kennaway's Select committee at the House of Commons.

The opposition of the Cheshire Lines Committee was continued.

Mr. CHAS. STEEL, the General Manager of the Great Northern Railway Company, and Mr. G. H. TURNER, the General Manager of the Midland Railway, spoke of the injury the proposed line would do to the existing railways.

Sir DOUGLAS FOX said he was the consulting engineer of the Great Central Railway Company and had, in 1893, carried out the Liverpool Overhead Electric Railway. That railway was formed to run over the existing dock railway, from end to end, and had the support of the Board, though it was now in the hands of a separate company. It was clear to him that whoever laid out the railway did not understand the local arrangements, otherwise the difficulty as to Salford could have been removed by running into a tunnel instead of on a high viaduct. In his opinion, by the introduction of electric traction there was good hope of attaining a high speed on ordinary railways properly worked, but he would never seek high speed in connection with the mono-rail. He did not wish to question the possibilities of electric traction. He believed it was the traction of the future, but did not think it should be applied to this railway, which was called a mono-rail but was really a railway of fire rails. If there was a settlement of a sleeper the train going at high speed would be derailed, with serious consequences. The brake question was a serious one. He was sure that the electric louvres would not have any appreciable effect.

Digitized by Google

By Mr. NUSSEY (a member of the committee): It was possible to reverse a dynamo. but he thought it would be a risky experiment. What would be the effect of stopping a train short at that speed of 100 miles per hour he could not say.

Mr. LITTLER, Q.C., addressed the committee on behalf of the Lancashire and Yorkshire and London and North Western Railway Companies, and evidence was tendered on behalf of the Mersey Docks and Harbour Board.

Mr. POPE, Q.C., addressed the committee on behalf of the Mersey Board: If the committee considered the scheme was sufficiently real to justify the attempt to try it; if they thought it was of public importance to see whether a speed could be raised by electricity from 60 miles to 110 miles an hour he had nothing to say, except that the interests of the dock were so superior to the public advantage, so much more important, that such a scheme should not be sanctioned to their injury.

Mr. BALFOUR BROWNE, Q.C., on behalf of the promoters, said with reference to the suggestion for a tunnel made by the Salford Corporation, they had considered the matter most carefully and they could show it was an impracticable scheme. The cost of construction would add £250,000 to the scheme, and the water-laden strata through which they passed would involve considerable pumping. Replying on the whole matter, Mr. Balfour Browne urged that the scheme had been thoroughly considered and was supported by the men of the two cities who had the interests of their towns at heart. Practically the same opposition was made then as was raised against the first railway in 1825. The whole question was, why should there not be another railway between Manchester and Liverpool. Electric traction was cheaper and quicker than locomotive traction, and every competent person allowed that a speed of 100 miles to 110 miles an hour is easily to be attained. Their opponents had not called a single person who knew anything about electricity, for Sir Douglas Fox had never made an electric railway. Then the Cheshire Lines said the proposed railway could not pay. But how could they say that? They knew that at present there was between Liverpool and Manchester 174 trams each day, which in a year run two million train miles and only carry one million passengers. Compare that with the Liverpool Overhead Railway, which carried nine million passengers every year, or with the results of the tramway service of Glasgow, and they would see the benefit of electric traction. The question of brake power was the only real objection that had been raised. Their opponents sneered at the louvre boards, but on the Lyons-Mediterranean Railway the system had been entirely successful. Then they had the Westinghouse brake, and as Mr. Cottrell had told them, it was possible to retard the train by short circuiting the motor, and so turning it into a dynamo. None of the landowners through whose land the railway passed opposed the bill. In concluding, counsel said England, which was the pioneer in the great enterprise of locomotion, was to-day behind other countries in relation to electrical power and electrical traction. The proposed railway was a new departure in locomotion—in the locomotion of the future. Electrical traction will be the motive power of the future. If their scheme could be shown to be commercially feasible—and they were willing to take the risk of that—it would be inaugurated for all time. It was, therefore, in the interests of England generally that he asked them to pass the bill.

After a short consultation, the CHAIRMAN announced the decision of the committee. He said: It appears to the committee that the monorail system which is suggested for the proposed railway is likely, when fully matured, to make an important contribution to the development of railway traffic at high speed. In certain important respects, however, the present scheme is seriously incomplete. More particularly, the evidence given before the committee has not satisfied them that a safe method has yet been found of applying effectively brake power to trains running at the high rate of speed proposed. Apart, however, from such considerations as the above, the committee are of opinion that the proposed line has been laid out without adequate and reasonable regard to existing interests, bearing in mind that the intermediate districts would not participate in any of the advantages of the railway. The Corporation of Salford would seem to have just cause of complaint in this respect, and the interference of the proposed line with the use of land at Liverpool acquired by the Mersey Docks and Harbour Board for the construction of additional docks has weighed seriously with the committee. The committee are of opinion that in all schemes put forward for giving access to the heart of great cities the question of underground approach ought to be considered and adopted where practicable. On these grounds the committee are of opinion that the preamble of the bill is not proved.

SOUTHPORT AND LYTHAM TRAMROAD BILL.

On Friday last week, a House of Commons Committee, presided over by Mr. C. Seale-Hayne, commenced the consideration of this bill, which is being promoted by the Southport and District Tramroad Co., for powers to construct an electric tramway from Southport along the coast about 5 miles, where it is proposed to cross the river Ribble by a conveyor bridge, thence to Lytham.

Mr. RAM, Q.C., for the promoters, stated that a bill to construct the proposed tramway was before the House last year. It was now proposed to cross the Ribble higher up the estuary. At the present time Blackpool, St. Annes, and Lytham were connected by tramways. Last year Parliament sanctioned the construction of a tramway from Southport to North Meols, whence it was then proposed to make a tramway on the surface of the sand to the estuary of the Ribble and across the river to Lytham. By the present scheme the tramway could be continued between 3 miles and 4 miles further along the coast from North Meols to Guide's House, where the conveyor bridge would be constructed across the Ribble. The height of the bridge would be 147ft. The tramcar would be carried across the river by means of a suspended travelling cradle, driven electrically. The Preston Corporation, who opposed the Bill, contended that the bridge would interfere with the navigation of the Ribble and assist accretions in the estuary, but Mr. Ram argued that there was no possibility of the proposed works damaging the navigation of the Ribble.

Sir GEORGE PILKINGTON, M.P., Ald. GRIFFITH (Mayor of Southport), and others gave evidence in support of the scheme.

Mr. J. T. WOOD, C.E., one of the engineers of the scheme, described the proposed works. The piers of the bridge would be behind the training walls of the channel, and therefore would not interfere with the navigable portion of the channel. The bridge would be constructed on open ironwork supports fixed in the sands, so as to form pier and landing-stage suitable for vehicular and pedestrian traffic. The bridge would connect the tramway running through Hesketh-with-Becconsall with that at Warton on the northern training wall of the Ribble, and was intended for the conveyance, upon a platform or car suspended from the girder, of tramcars, carriages, waggons, passengers, animals and merchandise. The cradle or platform of the bridge would be from 50ft. to 60ft. long, capable of carrying an electric car and trailer or a waggon-load of hay, or other produce, with two horses, to the total weight of 25 tons. About 1½min. would be occupied in traversing the channel, and there would be duplicate machinery in case of accident. Two similar bridges had already been sanctioned by Committees of the House this session, one between Widnes and Runcorn, spanning 1,000ft., and the other, promoted by the Newport (Mon.) Corporation to cross the river Usk. The height of the girder from which the cradle was to be suspended at Runcorn was 82ft., that at Rouen was 167ft. The promoters of this bill had offered to increase the height of their girder from 130ft. above spring tide to 147ft. (6ft. higher than the Tower Bridge across the Thames). Its construction would follow on the lines of the bridge at Rouen. From a small upper deck a man would keep a "look-out," and the cradle would be under exactly the same control as an ordinary electric tramcar under that of its driver. The cradle could be stopped at any moment and moved backwards or forwards as desired. All the equipment for working was in duplicate and so arranged that it could be worked separately or combined. In connection with the bridge at Rouen hand power had also been introduced, but it had never been used, nor were they likely to want it in crossing the estuary of the Ribble although it was provided. If the "look-out man" saw a vessel was likely to be in the way of the cradle as it journeyed across, he would, of course, not start from the pier until the vessel had got clear. Assuming the cradle stuck at any point of the bridge, it would occupy only 50ft. out of about 550ft., and a ship would have plenty of room to pass. Although the rods by which the cradle would be suspended would be 130ft. long the cradle would not swing. A gale of wind might cause the cradle to take a slightly curved course, but it would be perfectly steady. There never could be a pendulum motion. Statistics showed that only 1¾ ships navigated the Ribble per tide. In fact there was no traffic to interfere with. At Bilbao, where a similar bridge had been working for seven years, there was ten times the traffic. The cradle attached to Bilbao bridge had never been stopped for an hour, although it was confronted by the full force of the wind from the Bay of Biscay. The proposed tramway would join up with existing tramways, making a practically continuous electric line from Southport to Blackpool.

Mr. G. F. Deacon, C.E., Prof. Harcourt, C.E., Mr. George Aberneathy, C.E., and Mr. H. Graham Harris, C.E., gave evidence that the influence on the tidal flow such a bridge would have was so infinitesimal as not to be worth mentioning.

For the opponents of the bill,

Mr. A. FOWLER, C.E., resident engineer to the Preston Corporation, stated that the Corporation had spent about £1,200,000 in improving the Ribble for navigation and had constructed a dock at a cost of £200,000. They, therefore, desired that the navigation should not only be preserved but that nothing should be done which would be detrimental to it. A tunnel could be constructed in lieu of the bridge, and this would not interfere with navigation to the port of Preston, against which master mariners seemed to have an objection more or less sentimental. They were making provision for vessels with masts as high as 160ft. and 170ft.

Capt. LEWIS DAVIES and Mr. R. W. LEYLAND, shipowners, Liverpool, and other witnesses having given evidence against the scheme, Mr. Pember, Q.C., for the petitioners, said that, subject to the adjustment of certain clauses, he had agreed with counsel for the promoters that the bill should proceed so far as the preamble was concerned. That was subject to the condition that the promoters would undertake to make the girder of their bridge 177ft. instead of 147ft. high.

The Committee decided that the preamble of the bill was proved.

MANCHESTER CORPORATION TRAMWAYS BILL.

A Committee of the House of Lords (Lord Newton presiding) began on Tuesday the consideration of a bill authorising the Manchester Corporation to construct additional tramways in and near the city, and to confer further powers on the Corporation and neighbouring authorities.

Mr. LEWIS COWARD, for the promoters, explained that the Corporation were the owners of the tramways within the city, which at present were leased to the Manchester Carriage and Tramways Co., and were worked by horse traction. The lease expired next April, when the Corporation proposed to work the tramways, and to adopt the electric overhead trolley system. In 1898 the Carriage and Tramways Co. unsuccessfully promoted a bill to enable them to introduce electric traction and continue the working of their system in connection with the local authorities. Meanwhile the Corporation had come to an agreement with a number of local authorities, under which the Corporation agreed to work the tramways as one continuous system. Negotiations were, however, now in progress between the Corporation and the Carriage Co. on the subject. In 1899 the Corporation obtained further tramway powers, including that to work and take leases of lines outside the city, and were authorised to take leases of tramways in Failsworth, Droylsden, Audenshaw, Gorton,

Digitized by Google

Denton, Levenshulme, Heaton Norris, and Stockport. Since 1899 the Corporation had arranged with Stretford Council to lease their lines, but the agreement had not been actually signed, and negotiations were also pending with the Withington and Moss Side Councils. In the present bill the Corporation took power to arrange also with Middleton, Reddish, Prestwich, Whitefield, and Radcliffe. The bill would further authorise the construction of certain tramways within the city aggregating to 37 or 38 miles of single track. It was proposed to operate in a manner entirely different from that adopted by the Manchester Carriage and Tramways Co, who ran from the suburban districts to a central point in the city and back again by the same line of route. The experience of other cities showed that the proper course was to have through routes, running from north to south or from east to west. This was found a good means of regulating the traffic. The Tramways committee had a scheme of through routes under consideration. The British Electric Traction Co., who were undertakers of the Middleton Light Railway Order of 1898, among others opposed the bill. The borough of Middleton was, however, in accord with Manchester, and the latter would not make connections with the company's lines without its consent, The practical opposition, however, came from the frontagers, and he urged that the Corporation were of necessity the best judges as to the width of streets and similar questions.

Mr. BOYLE, chairman of the Tramways committee, gave evidence in support of the scheme. The electric cars, being without horses, would take up much less room than ordinary tramcars, and the through system of working would help the flow of traffic. It was proposed to have fixed stopping places for taking up and setting down passengers, and this also would be a great improvement. Some of the proposed lines were intended to be used as alternative routes.

On Wednesday the evidence included that of

Mr. J. McELROY, general manager of the Corporation tramways, who said that several of the proposed tramways in the central part of the city were absolutely necessary as alternative routes in case of breakdown on other lines. Upon a through system worked by electric traction alternative routes were indispensable.

The TOWN CLERK of Middleton stated that his Council had voluntarily entered into the agreement in regard to a tramway system connecting Middleton and Manchester, and he considered the arrangement would be for the advantage of the district.

Evidence on behalf of the Horse Owners' Union and other petitioners was then taken, and the bill was passed as amended. It was announced that an arrangement had been arrived at with respect to the bill promoted by the Withington District Council for the construction of tramways.

BLACKPOOL, ST. ANNE'S, AND LYTHAM TRAMWAYS BILL.

On Tuesday a House of Commons committee, presided over by Mr. W. Holland, considered this bill, which is promoted by the Blackpool, St. Anne's, and Lytham Tramways Co., and seeks power to construct a double line of tramways between Blackpool and Lytham.

Mr. MELLOR, for the promoters, explained that the company were anxious to increase the powers already conferred upon them. The existing line had been open since 1898, and gas traction had been used, but it was found necessary, owing to the rapid development of St. Anne's-on-Sea and Lytham, to increase the tramway facilities and to adopt electric traction. Negotiations were proceeding with one of the objectors, the Blackpool Corporation, with the object of coming to an agreement. Other objections was to the construction of a double line, but arrangements had been made for widening the road so far as concerned the part affecting the petitioners. At present the trams were permitted to run at eight miles an hour, but the company asked to be allowed to increase this to 12 miles. The Board of Trade had sanctioned the increased speed. After hearing evidence, the committee found the preamble of the bill proved.

HUDDERSFIELD CORPORATION TRAMWAYS BILL.

The Select Committee of the House of Commons, presided over by Mr. Jeffreys, on Tuesday reconsidered the tramway portion of the bill, in respect of which the bill had been recommitted. The tramway extensions to Holmfirth, Holmbridge, New Mill, Mirfield, Kirkburton, Marsden, and Brighouse, were rejected by the committee on the ground principally that the subject of Municipal Trading was about to be considered by a Joint Committee of both Houses of Parliament, and also because they thought the proposal of the Huddersfield Corporation to construct tramways through outside districts, which, although consenting, were not contributing to the cost of the scheme, would infringe some of the rules of Parliament. The Chairman intimated that the House of Commons had now relieved the committee of this difficulty by authorising the committee to reconsider the bill in respect of the tramways lying outside the borough.

Mr. BALFOUR BROWNE, Q.C., for the Corporation, said the opposition of the Lancashire and Yorkshire Railway Co. to the outside tramways had been withdrawn. He cited various precedents in favour of the proposed extensions, including Halifax, Bradford, and Glasgow. If the borough of Huddersfield were not in the centre of the whole district, it was possible that some great traction company might come in and supply the wants of the outside areas, but under present circumstances, with Huddersfield possessing the key to the situation and all the best paying part in the centre, it was impossible for any body to supply the tramways for the outer districts except the Corporation. The Corporation did not want to do that at a loss, and he thought that the committee would be convinced that these tramways could be constructed and worked at a considerable profit. Owing to the introduction of electric traction, a great many difficulties in regard to tramways had been removed. Evidence was then heard, and the committee passed the preamble of the bill in respect to the outside tramways portion, and the bill was ordered to be reported with the tramway extension clauses re-inserted.

MERSEY AND WIRRAL RAILWAY BILLS.

The Committee of the House of Lords, presided over by Lord Morley, on Friday passed the Bills promoted by the Mersey and Wirral Railway Co.'s in which powers are sought to work their undertakings by electricity, and, if found expedient, to form a joint committee for constructing joint generating stations, and the proposed joint committee are empowered to borrow £500,000 for that purpose. In addition the Mersey Co. are empowered to raise £428,750 by the issue of further redeemable debenture stock for their own undertaking, whilst the Wirral Co. also obtain £240,000 additional capital powers.

HALIFAX CORPORATION TRAMWAYS BILL.

A Select Committee of the House of Commons has approved this bill. For the promoters, Mr. BALFOUR BROWNE, Q.C., said the Corporation had worked the existing tramways successfully during the last two years, having made nearly £6,000 profit and earned 7½ per cent. on the capital outlay. The lines already authorised were over 77 miles in length, and the proposed extensions were 10 miles within and 27 miles 6 furlongs outside the borough. The lines would go through 15 urban and rural districts, and the borough of Brighouse, but all the local authorities were in favour of the scheme. The estimated cost of the extensions was £326,800. The tramways carried 7,000,000 passengers per annum.

The CHAIRMAN said the principle of the extension of tramways outside boroughs had already been sanctioned by Committees of Parliament, and the Committee would only require evidence as to the cost of the lines, their local necessity, and the consent of the municipal authorities through whose districts the lines were taken.

Ultimately the clauses were passed by the Committee.

LIVERPOOL OVERHEAD RAILWAY BILL.

As the Liverpool Overhead Railway Co. have inserted new clauses in their bill for powers to supply electricity the Liverpool Corporation have petitioned against the bill.

MUNICIPAL TRADING.

The Lords and Commons Joint Committee on Municipal Trading held their first public sitting on Tuesday. The Earl of Crewe presided, and there were also present Viscount Peel, Lord Rothschild, Sir L. Lyell, Sir W. Foster, Mr. L. Fry, Mr. Grant Lawson, and Mr. Hobhouse.

The first witness called was Sir COURTNEY BOYLE, permanent secretary of the Board of Trade. In cross-examination by the Chairman he said that while gas, water, and tramways were regarded by Parliament as monopolies, electric lighting had always been on a different footing. The Electric Lighting Act of 1888 contemplated competition, and the plan adopted by the Board of Trade, after the passing of that Act, was to permit competition between two bodies of undertakers, but not more. In regard to gas, he could not trace any great advantage to the consumer in point of price in being supplied by a local authority as against a company, but there was a slight advantage.

The CHAIRMAN: As to electric lighting, how many corporations own electric lighting installations?—There is a hiatus in our statistics there. I think that about 300 are authorised, but only about 99 are working, the rest being authorised, but in suspense. Witness went on to say that he did not think he ought to go into the question of the supply of electric power, as a Special Committee of the House of Commons was now engaged in dealing with it. He might say, however, that before the Act of 1888 was passed a considerable number of local authorities obtained electric lighting powers which they did not exercise, and thus kept others out of the field. It was with a view of remedying this state of things that the clause which permitted competition was inserted in the Act of 1888. As to the effect of allowing a local authority to supply electricity outside its own district, he said the result would naturally be to make the local authority a trading company outside its own district. Whether it was desirable that this state of things should be allowed or not he did not express an opinion. Some local authorities had made applications to Parliament for permission to supply electric lighting fittings and other goods to the public. He thought that these applications had a tendency to increase, but the Board of Trade had set their faces against them very strongly. The Board were willing to authorise the supply of machinery if such supply was necessary and incidental to the supply of electricity, but not otherwise. For instance, the provision of a good supply meter (when one was found) might well be entrusted to corporations, but not burners and things of that kind. The wiring of houses for electric lighting had never been entrusted to corporations. The corporation asked for leave to provide and maintain omnibuses in connection with the tramways. That was a new power, and one which had been resisted. Another corporation wished to provide a refrigerator and cold-air store. One wanted to supply bathing tents, and another to provide Turkish baths. At Battersea it was proposed to start a printing establishment, but he did not think it was carried out. Other cases where when powers had been sought to erect dining-rooms and to provide and make a charge for the use of apparatus for games in recreation grounds. He could not tell if there was a municipal authority which owned a dock of its own, but he should be disposed to say there was not. Some municipalities had power to supply electric current outside their own area. The power was either given direct by Parliament or it had been acquired by the absorption of powers possessed by others. Several instances had arisen

Digitized by Google

of this transfer of powers. In some instances Parliament had authorised the supply of electricity in bulk to outside districts; but, as a rule, the Board of Trade tried to confine a concession asked for to a given geographical area. He knew of no instance where a forcible transfer had been permitted.

Questioned as to the policy of allowing local authorities to work tramways outside their own boundaries, Sir COURTNEY BOYLE said it was a matter for consideration whether it would not be better to have tramways worked by joint boards, instead of allowing local authorities to go outside their own boundaries. A local authority which made or worked tramways outside its own district became a trader outside that district. If it made a profit, that profit would come out of a district under the jurisdiction of another local authority; while if it incurred a loss, its ratepayers would have to make it good for the benefit of the outside area. The ownership of tramways by municipal bodies was authorised by the Act of 1868; the working of them by those bodies was of comparatively recent date. It began with the passing of the Glasgow Act. After that Huddersfield got power to work its lines because no lessee could be found to take them up. For some years the Board of Trade refused this power to corporations. Then separate applications were made to Parliament, and as the result of a conference between the authorities of Parliament and the Board of Trade it was decided to grant the powers asked for, and the Huddersfield clause was introduced in many cases. There were now, he believed, 17 corporations working their own tramways. The tendency on the part of local authorities to go outside their own areas was a growing one. Circumstances had forced it upon the attention of Parliament, and no definite policy had yet been thought out.

The CHAIRMAN: Do you trace any association between the demand for these powers and the invention of electric traction?

WITNESS: Yes, and if electric traction spreads, as I hope it will, we may expect that tramway systems will become larger than they are—that is to say, that the lines will become larger.

And it is desirable that the supply of electricity should be made from some central point?—Yes.

That, as a matter of fact, is likely to lead to fresh applications being made?—Yes.

Lord ROTHSCHILD: And larger systems being constructed?—Yes. Witness added that, so far as the Board of Trade figures went, they showed that corporations as a whole had done very well in working tramways. He should be sorry if anything he had said in his evidence were construed into a disposition to distrust local authorities. The point he wished to make was merely that when such authorities went out ide their own districts to trade Parliament should consider on what principles, with what limitations, and with what organisation they should act.

Mr. GRANT LAWSON: As an alternative to allowing municipalities to go outside their own areas to extend their tramways, you suggest they might work by joint agreement. How do you suggest that the accounts should be kept in that case?—It would be a difficult matter of adjustment, but I don't think it would be a greater difficulty than is overcome every day by the Clearing-house.

Would you do it by running powers?—I think that would be a very good way of doing it.

Sir L. LYELL: When a municipality buys out an electrical undertaking which is partly within and partly without its own area, what becomes of the statutory right of a local authority to purchase the undertaking outside the municipal area?—It is not destroyed.

Sir W. FOSTER: With reference to the question of tramways outside the area of a municipality, has it occurred to you that in many instances, if some such scheme as you suggest of a joint board to supervise the working of the whole area where not initiated, you would put a great incentive upon a large municipality to extend its boundaries, and to incorporate small local authorities?—That is a point which has not been mentioned to-day, but it has certainly been present to my mind, and it is one that will have to be considered, because I am quite certain there is a tendency on the part of great corporations to grasp outside areas.

The Committee then adjourned till to-day (Friday).

MUNICIPAL, FOREIGN & GENERAL NOTES.

Aldershot.—The Council have determined to carry out the terms of their provisional order and tenders are to be invited for electric lighting plant.

Aylesbury.—A committee was recently appointed to visit the electricity works at Harrow, Windsor, and Wycombe, and to report upon the question of carrying out the provisions of the Aylesbury Electric Lighting order. The committee report that in all the places visited there exists a demand to an extent which will not be equalled in Aylesbury for some time at least, but that unless favourable terms can be obtained from a transferee the proper course will be for the Council to themselves carry out their powers

Battersea (London).—The Vestry on Wednesday resolved to oppose the London County Council Tramways (No. 2) bill in the House of Lords, in order to obtain certain amendments. The Board of Trade recently granted a provisional order to the County of London Co. for a portion of Battersea, and the Special Parliamentary committee reported that they had suggested to the Board that they should impose on the company conditions requiring them eventually to cease supply in those portions of their existing area which, under the re-arrangement of boundaries, will be transferred to the new borough of Battersea. The committee had received a letter from the Board, stating that the matter is not one which can be dealt with in connection with the grant of the order, but that the Board are considering the question of the re-arrangement of the electric lighting areas with the view of making them coincide with the new borough boundaries, and hope to be able to take such steps as will give the Council of the new borough of Battersea full control of the supply of electrical energy within the area under their jurisdiction.

Bermondsey (London).—A report has been prepared by the consulting engineers (Messrs. Kincaid, Waller and Manville) in reference to the specification for the supply of feeders and distributing mains for the Vestry's electric lighting extensions. In their original report they proposed to lay distributing mains for the supply of 4,000 8c.p. lamps alight, and they now suggest that in extending the mains provision should be made for double that number or the equivalent of 10,500 lamps connected to the mains. The total cost of the mains and feeders, together with conduits, street boxes, &c., is put at £6,000. The Electric Lighting committee having considered the report thought it would be desirable to include Long-lane and Southwark-park-road in the streets proposed to be lighted by arc lamps, and that alternative prices should be obtained for the laying of larger mains so that a supply could be given to the whole of the new borough of Bermondsey. The committee had accordingly obtained a further report from the consulting engineers, who estimated that the cost of the additional works would amount to £3,310. The committee recommended the Vestry to approve the reports and to instruct the engineers to prepare a specification, and that tenders be invited for carrying out the works. This recommendation was adopted by the Vestry on Monday.

Bill Withdrawn.—The London, Walthamstow, and Epping Forest Railway Co. (which was to have worked electrically) give notice of intention to promote a bill to authorise them to abandon the railways and works covered by their Acts of 1894 and 1895, and to authorise the dissolution of the company.

Birmingham.—The first report of the Corporation Electric Supply committee was presented on Tuesday. The accounts for the year ended December showed a gross profit of £23,489, an increase of £5,962. 11s. over 1898. There was a steady increase in the demand for electric current, for during the past three months the increase was at the rate of 35 per cent. per month, compared with 30 per per cent. last year. The Birmingham company had set aside annually a certain sum for reserve, and the committee have decided to continue this fund. The amount on Jan. 1 was £25,856. 8s. During 1899 the total units sold amounted to 2,252,692, against 1,722,327 in the previous year, an increase of 30·8 per cent. The lamp and motor additions on the various circuits, reduced to a 16 c.p. factor, amounted to 12,694, bringing the total to 62,705, against 50,011 in 1898, an increase of 25·3 per cent. The gross revenue during 1899 amounted to £43,245. 18s. 9d. against £33,462. 18s. 11d. in 1898, an increase of 29·2 per cent. The committee have decided that, as the financial year of the Corporation ends on March 31, the accounts shall be made up to that date in future. The statements for the last three months show a balance, after providing for interest on the £500,000 loan, of £2,707. 4s., and the committee have decided to apply this balance towards meeting the cost (estimated at £6,200) of relaying certain of the older mains in the centre of the city. The mains laid by the company were of two kinds, copper strips in open culverts, and mains laid in solid bitumen, and the committee have decided to take up the copper strip and employ the solid system. The chairman (Mr. Johnstone) thought the report was one with which the Corporation might be well satisfied, and there was no doubt the electric supply department would take its place alongside the gas department, and in the course of a year or two furnish something in aid of the rates. The report was adopted without discussion.

We have received a copy of the *Birmingham Magazine*, which is described as an "electrical" number. A brief historical *resume* of the events which led up to the introduction of public and private lighting is given, more particularly in connection with their application to Birmingham. This retrospect is followed by an illustrated account of the City of Birmingham electric supply undertaking recently acquired from the Birmingham Electric Supply Co., Limited. The magazine is a very creditable production. It is, however, an expensive publication at 1s.

Boulogne.—The electric tramways established in this popular resort are very prosperous, and the line is at present being extended to Wimereux. Further extensions are projected.

British Columbia.—The Stave Lake Power Co. (Ltd.) has been recently incorporated in Vancouver (Columbia), with a capital of £200,000. The company has acquired a waterfall on the Stave River, 42 miles from Vancouver, where power will be generated and transmitted to that city. The company is about to expend £100,000 on new plant, apparatus and material.

British Institution of Draughtsmen—At the half-yearly meeting of the Council of this Institution, on 14th ult., the resignation of Mr. J. Gillaird, London, as hon. secretary and treasurer, was

Digitized by Google

accepted. Mr. C. L. Groundwater, Manchester, and Mr. J. F. Wakeham, Newcastle, were unanimously elected hon. secretary and hon. treasurer respectively. It has been decided to alter the title of the Society from the British Association of Draughtmen to that of British Institution of Draughtsmen.

Cable Manufacture in Spain.—A company, entitled La Sociedad de Cables Electricas de Algorta, has been formed at Algorta, Vizcaya, to establish works for the manufacture of electric cables.

Carthagena (Spain).—A concession has recently been granted for the construction of an electric railway from Carthagena to Cape Palos, passing through the mining and smelting district, with a branch to Portman. Construction works are to commence immediately.

Cheltenham.—The order (see our last issue) recently placed by the Corporation with Messrs. Witting Bros. (Ltd.), 49, Cannon-street, London, E.C., for a standard railway generator has been repeated. Two over-compounded machines are to be supplied, arranged for coupling to Belliss engines, the combined sets furnishing current to a local light railway.

Chicago.—A complete electric lighting and power plant has been put down at the great produce packing establishment of Messrs. Armour and Co. The new plant, which has cost over £200,000, is stated to be the largest isolated set of electrical plant ever put into operation. Ice machines, refrigerators, hoisting contrivances, meat trolley lines, machine shops, &c., are all to be worked by electric motors.

Dalkeith.—Proposals of the Electric Supply Corporation for the erection of electricity works for Dalkeith and Eskbank have been submitted to the Burgh Commissioners, and a committee has been requested to report.

Dover.—The accounts of the Corporation electric tramways for the past year show a profit of £3,155, a considerable increase on the preceding year.

Dunfermline.—A report on the proposal to erect joint electricity supply and refuse destructor works has been prepared by the burgh engineer (Mr. A. W. Bell).

Edinburgh.—On Tuesday the Corporation discussed a recommendation of the Electric Lighting committee that the charge for electric current, from May 15 next be 3¾d. per unit, for each public lamp £13 per annum, and for motor power as at present (1½d. per unit). Bailie Mackenzie said that for the first time it was his duty to ask the Council to raise the charge for electric current for private lighting. They began five years ago with a charge of 6d. per unit. A year later this was reduced to 5d., the following year to 4d., and two years ago to 3½d. Last year there was no change. The circumstances which necessitated the rise were the great increase in the price of coal and the large expenditure put upon the undertaking by the commencement of the new M'Donald-road station. Two years ago, when the present rate of 3½d. was fixed, coal cost 7s. 8d. per ton. This year the price was 12s. 10d., and at M'Donald-road 12s. 6d., which would make a difference on the year's consumption of £7,750. Contracts had been made for three months only, as they were advised that in all probability the price would fall, but meantime it was safest to count on the full price for the whole year. Separating their two stations at Dewar-place and M'Donald-road, and making, as it were, an estimated balance-sheet for each, they come out as follows for 1900-1901: Of the total estimated expenditure of £45,715, M'Donald-road must be debited with £14,599, and of £40,000 for interest and sinking fund the proportion was £11,292, total £25,891. Of the total revenue of £90,000, M'Donald-road could only be credited with £22,900, leaving a loss of £2,991 on that part of the undertaking. On Dewar-place there was an estimated profit of £7,276, leaving only £4 285 surplus profit on the whole undertaking. Some members of the Council had suggested that the rise in the price should be one halfpenny per unit, but the majority of the committee thought otherwise. In view of the resolution of the Council to make up the reserve as soon as convenient, the committee thought a light rise in the price would be sufficient, as undoubtedly the M'Donald-road station as soon as reasonably full would show a balance-sheet similar to Dewar-place, and in all probability coal would fall in price. The Portobello part of the undertaking had shown a loss for the year of £844, and for the coming year it was estimated the loss would be about £700. Some members of the committee expressed a fear that too little provision was being made for reserve, but it should not be overlooked that, of the money spent during the last two years (over £300,000), a large part had been expended on land, buildings, subway, copper strip, and Callender cable; and the machinery and plant obtained in these two years might be said to be only just started, so that in reality it was only the more perishable portions of the early plant that need be considered at the present stage. The recommendation that the public lighting be reduced in price to £13 per lamp was on the understanding that an increase of about 72 lamps was made. With the rise to 3¾d. or even 4d. for light, which would give an average of 3½d. the charge was still about the lowest in the kingdom, there being only four places where the average price was a shade under 3½d. There were, however, 15 places where current for power was 1½d. per unit and under. There had been the most gratifying increase in current for motor power in the last two years. The engineer estimated the output for private consumers this year at 6,000,000 units, and for public lighting 1,300,000—in all, the enormous output of 7,300,000 units. The total 8 c.p. lamps or equivalent at May 15 was 296,569, with about 20,000 more applied for. The number actually joined during the year was 69,832, the largest that they, or, he believed, any other electrical undertaking had ever connected, and over 2,000 more than Glasgow. On the five years' working there had been a total capital expenditure of £595,000. There had been repaid to sinking fund £42,600, to which £20,750 further would be added this year; placed to reserve £14,600, not including this year's surplus; paid to the general improvement account £10,374; paid in local taxation about £10,000, and paid to the general expenses of the City Chambers, &c., £5,387. A large proportion of the latter charge, as well as the £4,451 to be paid for local rates, should be looked upon as a fair return to the ratepayers—as distinct from users of electric light—for the security of the rates. Treasurer Cranston moved an increase to 4d. per unit. Mr. Auldjo Jamieson supported the amendment, and criticised severely the policy of municipalities generally in the piling-up of their public debts. He warned the Council against some of its financial methods, whose tendency was to bind a heavy burden on the ratepayers. By 37 votes to 5 it was decided to reduce the public lighting from £14 to £13 per lamp, and by 29 to 13 to increase the charge per unit for electric energy by one farthing (to 3¾d.).

Electric Traction and Lighting Enterprise in Spain.—Owing to the electric lighting of Corunna being practically a monopoly in the hands of the local gas company, very little advance has been made in installation work, and the charges for current have ruled very high. To obviate this state of affairs the Sociedad Co-operativa Electrica Coruñese has been established to instal and supply electric light for public and private uses at lower rates than have previously prevailed. Besides the Co-operativa Co. another undertaking has been established, with a capital of 2,150,000 pesetas, for supplying electric current in Corunna. This latter company has been established by Bilbao capitalists, and the capital was largely over-subscribed. Water power has been acquired at some distance from Corunna. This undertaking is awaiting final consent from the municipality.

At Villagarcia an electric supply company has been established, entitled La Electra de Segad. This company obtain about 1,000 H.P. from a power station at Caldas de Reyes. The towns of Villagarcia, Carril, Caldas, Cesures, Padron, and Cambados are supplied with electric current by this company. The shareholders are French and Spanish. The lamps used are from Budapest, the cables were manufactured in France and Germany, and the generating machinery is wholly French.

A concession has lately been granted to a German syndicate for the construction of an electric tramway between Cadiz, San Fernando, and Chiclana, the estimated outlay on these works being put at 2,000,000 pesetas (at 35 pesetas to the £=about £57,000). German energy and capital has recently converted the tramway system of Seville from horse to electric traction.

Electric Traction in Australasia.—Mr. W. G. Bingham has obtained a concession from the Adelaide (South Australia) City Council for the construction of electric tramways in Adelaide. A similar concession was recently obtained by Mr. Bingham from the Auckland (New Zealand) Corporation.

Electricity in Baking.—Messrs. J. W. Henderson & Co., South Shields, recently decided to introduce electric machinery for kneading purposes in connection with their bakery. Current is supplied from the town mains to a 2 H.P. electric motor for driving the kneading machine.

Engineering Magazine.—The May issue contains articles on "Electrical Appliances in Military Operations," "Works Management for the Maximum of Production," "Labour Questions in England and America," and "Manufacturers' Associations, Labour Organisations, and Arbitration."

Exhibitions.—An exhibition of electrical novelties and apparatus will be held at Kiel, between June 16 and July 1, in connection with the eighth annual meeting of the Verband Deutscher Elektrotechniker, which will be held in the town between June 17 and 20.

An electrical exhibition will be held in Vienna, in 1903, in connection with the celebration of the twentieth year's existence of the Elektrotechnischer Verein of Vienna. Prof. Carl Schlenk has been designated president.

Fenton.—The Council has been informed by the Hanley Corporation that they could not at present entertain the request to supply electric current to Fenton for a period of 10 years.

French Submarine Cable Exports.—The Société Industrielle des Téléphones exported during 1899, from its extensive works at

Digitized by Google

Calais, 220 miles of submarine cable for a destination not given, and also 160 miles for Venezuela and 170 miles for the United States. These exports show a considerable increase over 1898.

Gosforth.—The Council have entered into an agreement with the Newcastle-upon-Tyne Electric Supply Co. for a supply of current in the district, at a price not to exceed that charged in Newcastle.

Govan.—Mr. James Brown, burgh electrical engineer, in a report just presented, approves of the principle of allowing the National Electric Wiring Co. to undertake the wiring of consumers' premises on the easy-payment system on the ground that it would secure an increased demand for current. Mr. Brown, however, considers the charge of 1d. per unit for all current used a high one, and proposes that it shall be 1d. per unit at maximum demand rate, and ½d. per unit after.

Granada (Spain).—It has been decided to erect a colossal cross upon the summit of El Pichacho de la Veleta, and the arms of the monument are to be lighted by electricity in order that the cross may serve as a beacon, and be seen afar at all times both by land and sea. The movement for the erection of this monument is receiving enthusiastic support in Granada and Madrid.

Greenock.—The Corporation have received 53 applications for the position of burgh electrical engineer vacant by the resignation of Mr. S. E. Fedden. This number has been reduced to seven, from whom a final selection will be made.

At present there are 97 customers of the electricity department, representing an equivalent of 6,258 8 c.p. lamps connected for private lighting.

A special meeting of the Police Board will be held on 29th inst. to consider the terms of the agreement for leasing the tramways within the burgh to the Greenock and Port Glasgow Tramways Co. The lease is for 28 years, with option to the board of terminating it at 14 or 21 years on six months' notice. The company bind themselves to reconstruct, equip and maintain their own and the board's tramways, so far as possible, as a double line, to erect the necessary electrical equipment on the overhead trolley system, and to complete the work by May 15, 1901. An annual sum of £1,200 is to be paid as rent in lieu of maintenance of streets, £450 per annum for the 4½ miles of tramway within the burgh, and in addition the cost of repairing all disturbances to the roadway occurring from reconstruction, repairs or renewals of the rails, &c. Also one-third of the net profits on the tramways within the burgh in excess of the cumulative dividend of 6 per cent. per annum on the capital is to be paid to the Board. Electrical energy is to be taken from the Board for working the tramways within the burgh, and so far as the company lawfully may within the adjoining burghs of Port Glasgow and Gourock, one of the conditions being that the company shall pay the board for a minimum supply equal to 500,000 units per annum at 1½d. per unit, the company also to pay for the use of poles erected by the board for street lighting, for the use of feeder-ways, pipes, or other works belonging to the board. The company must maintain a ten minutes service of cars during 16 hours per day, the charges not to exceed 1½d. for each half-mile, and 3d. for the 4½ miles within the burgh, and special service is to be provided for workmen.

Halifax.—The North Bridge Stump Cross electric tramway section has been completed and is ready for Board of Trade inspection. The line will be opened for traffic next week.

Hammersmith (London).—The Electric Lighting committee have issued the accounts of the electricity department for the year ended March 25. The chairman of the committee (Mr. A. Ebbs) stated that the capital expenditure had increased from £72,425. 11s. 6d. to £104,498. 8s. 11d. Of this sum £80,000 is the expenditure for the year to March 25. On this capital the profits have amounted to £5,894. 11s. 6d., equal to a dividend of over 7 per cent., and this notwithstanding the reduction in price of current which took effect last June. The total sales were £13,835. 11s. 4d. Mr. Ebbs said he had hoped they might this year have discontinued the use of the demand indicators, and have made a uniform charge for electricity. There was, however, a doubt whether this might not have increased the demand upon the station plant without corresponding increase of revenue, and also some difficulty in suggesting a fair compensation to long-hour consumers. The committee had, therefore, decided to carry forward the balance of £2,335. 19s. 9d. The quantity of current generated had been 1,247,730 units, sold 891,451 units, used on works 252,389 units. The number of public lamps was 150, and the maximum demand 700 kw. The report of Mr. G. G. Bell, the engineer and manager, states that the number of consumers had increased from 275, with 19,390 8 c.p. lamps, to 464, taking 26,365 8 c.p. The average number of lamps per consumer had decreased from 70 to 56, due mostly to the number of small flats in the parish wired for electric lighting. The department has received £3,375 for lighting and maintaining the 150 street arcs, a reduction from 3¼d. per unit to 2·9d. per unit; 63 additional arcs were added during the year. For private lighting the 620,078 units sold produced a revenue of £10,274. 5s. 7d., or barely 4d. per unit. The average lighting hours of the lamps had increased from 840 to 900 per annum, but owing to the reduction of practically ½d. per unit in the price, the annual revenue per lamp had been 9s. against 10s. 10d. the price paid for current in Hammersmith being the lowest but one in the London district. The total cost of generation, distribution, &c., was £7,764. 14s. 11d, or 2·05 per unit, a decrease of nearly ½d. per unit, being 56·5 per cent. of the revenue, leaving a gross profit of £5,974. 0s. 10d., or 43·5 per cent. towards interest and sinking fund charges. The result of the year's working was a net profit of £1,615. 4s. 8d., after deduction of interest and repayment of capital. The machinery now installed and in working condition is equal to supply a further 10,000 8 c.p. lamps, allowing ample margin for reserve.

Hunslet.—The District Council have been asked to sanction an application for a provisional order.

Ilkeston.—An inquiry was held last week into the application of the Council to borrow £18,271 for electric lighting. The town clerk (Mr. W. Lissett) said that in 1899 provisional orders were obtained to authorise electricity supply, and also to construct tramways. The present loan was for electric lighting. The estimated cost of the generating station was £28,452, and this was to be divided equally between the tramways and electric lighting schemes. This showed £14,226 to come out of the loan applied for that day, the balance of £4,045 being for the laying of mains, &c. The consulting engineer (Mr. V. B. D. Cooper) gave technical details, and pointed out that it was intended to erect a refuse destructor. The cost of generation would not exceed 2d. per unit. The number of lamps already applied for was equivalent to 3,100 8 c.p. He had no doubt that in a short time the whole of the 6,000 lamps, the capacity of the proposed station, would be taken up.

Insurance.—The Shoreditch Vestry are about to issue invitations to the metropolitan local authorities to appoint delegates to attend a conference to consider the question of municipal fire insurance. The letter states that the Vestry have recently had under consideration the large premiums exacted for insurance, especially for electricity works, and as they now pay £450 per annum for insurance, the sum total of municipal insurance of local authorities in London must have reached an amount sufficiently large to warrant the establishment of some scheme for mutual insurance with every prospect of success. The Corporations of Glasgow and Nottingham obtained in 1898 power to insure their own property, and a combination including the large number of municipal properties in London would (the Vestry urges) seem to offer special chances of success, and reduction of the present premiums. The Vestry have accordingly decided to call a conference of metropolitan local authorities to discuss this question, and the best means of carrying into effect some such scheme.

Inverness.—A special meeting of the Council was held on Tuesday to consider the question of tenders for electric lighting plant. It will be remembered that the consulting engineer (Mr. E. G. Craven) recently recommended the acceptance of the tender of the Brush Co. for the supply of the whole of the generating plant, but the Council referred the matter back for further consideration as they thought that by letting the tenders in sections a saving would be effected. After a discussion, which lasted over three hours, it was decided, on the motion of Provost McBean, to refer Mr. Craven's scheme to a neural expert for report.

Jaroslaw (Russia).—A company, entitled the Société des Tramways de Jaroslaw, has been formed in Belgium, under the auspices of the Compagnie Generale de Traction et d'Electricité, with a capital of £100,000, for constructing electric tramways in this town.

Keighley.—An inquiry was held here on Wednesday into the application of the Corporation to borrow £45,000 for electric lighting. There was no opposition.

Kilmarnock.—The question of a site for the proposed electricity works has been referred back to the Electric Lighting committee for further consideration. At a special meeting of the Council last week the consulting engineer (Mr. W. A. Bryson) submitted plans and specifications of his electric lighting scheme. Discussion arose as to the suitability of the proposed site at Riverbank, Riccarton. Mr. Bryson stated that the site would involve an increased cost of about £2,000 for copper compared with a more central site, but the buildings could be easily altered to suit the electricity station.

Lewes.—The Corporate seal has been fixed to the deed of transfer of the Lewes electric lighting order to the County of Sussex Electric Power Distribution Co.

Light Railway Orders.—The Light Railway Commissioners have submitted the Gateshead and District Light Railways order to the Board of Trade for confirmation. Objections by June 9.

The Board of Trade have approved the Cheltenham (extension) light electric railway order.

Light Railways.—An inquiry was held on Monday at Westminster by the Light Railway Commissioners into the application of the Middlesex County Council for permission to construct electric tramways from Harlesden, through Sudbury, Wembley, and Harrow on the one side, and from Southgate to Finchley on the other. The total length of the lines is about seven miles, and the cost of con-

Digitized by Google

struction and equipment was estimated at £117,000. Evidence having been given in support of the scheme, the Council withdrew two schemes for lines from Harrow to Watford, and Mr. Cripps, Q.C. (who appeared for the Council) incidentally mentioned that the differences between the Council and the North Metropolitan Tramways Co. (who were joint promoters of the scheme which the Commissioners had passed) would soon be settled. The inquiry was adjourned, the chairman stating that the Harlesden to Stonebridge section was passed.

An inquiry will be held at Leeds on June 7 into the application of the British Electric Traction Co. to construct light electric railways in certain districts of the West Riding of Yorks. One of the applications refers to Morley and district, another is for an extension of the Spen Valley, Dewsbury, and Ravensthorpe tramway scheme by constructing a line from Cleckheaton to Hightown, and to extend the projected line in Dewsbury through Savile Town, Thornhill Lees, and Thornhill, to the Combs.

The International Electric Traction and Power Syndicate propose to apply for powers to construct a light (electric) railway between Warrington and Runcorn.

Lincoln.—An inquiry was held here on Friday into the application of the Corporation to borrow £6,000 for electric lighting extensions. The deputy town clerk said that two loans had already been sanctioned—£20,650 in 1897 and £19,000 in 1899, of which £4,500 was still unexpended. The present loan was for laying cables in the southern part of the city. There are at present 200 customers of the electricity department, and the capacity of the station is about 18,000 8 c.p. lamps. The city electrical engineer (Mr. C. S. Vesey Brown) gave technical details.

Lissa (Austria).—The Gubavica Falls, near Almissa, on the Cetina, which, when regulated, will supply many thousand horse-power, is being regulated by a Vienna company. Already numerous applications for water power for industrial purposes have been made, and as the Government has lately constructed a fine iron bridge on the Cetina and made good roads in the adjacent district, a large development of this extensive source of power is likely to follow immediately. The industries in this neighbourhood are chiefly in the hands of foreigners, on account of want of local capital and enterprise.

London County Council.—At Tuesday's meeting the recommendations to double the existing tramway lines at Battersea, Wandsworth, &c., and to construct them for electric traction, as mentioned in our last issue, were approved, as was also the recommendation not to appeal against the decision of the Light Railway Commissioners in respect to the Council's application for powers to construct light railways at Deptford, Shooters Hill, Lewisham, and Clapham.

The Highways committee reported that in view of the probability of the London County Tramways (Electrical Power) bill becoming law this session, they had in preparation the specification and form of contract for the supply of rails, &c., which would be required in connection with the reconstruction of two sections of the Council's tramways (Westminster Bridge and Tooting, and Blackfriars Bridge and Kennington). Having consulted Prof. A. B. W Kennedy and Sir David Dale, the committee recommended that, as regards contracts for the supply of the rails, fish-plates, &c., required in connection with the reconstruction of existing, and the construction of new, tramways, the operation of the Council's standing order No. 212 be suspended so far as to permit of the omission of the usual clauses relative to hours and wages, and the insertion of a special clause as follows:—

All wages to workmen for work executed under this contract must be paid at the rates arranged between the employers and workmen in the rail trade in that part of the country where the order is placed. The Council reserves power to cancel this contract, so far as relates to any part of the articles specified therein not totally or partially manufactured, at any time on one week's notice, should it be proved to the satisfaction of the Council, after hearing both parties, that lower rates than the standard rates of the district have been, or are being, paid in the execution of this contract.

This was agreed to.

Long Distance Telephony.—It is announced that telephonic communication will shortly be established between St. Petersburg and Warsaw.

Lynn.—A loan of £2,500 has been sanctioned for electric lighting extensions.

Manly (N.S.W.).—The Council have resolved to ascertain the cost of lighting the district electrically, as the contract for gas lighting is about to expire.

Melrose.—Proposals for the erection of electricity works having been submitted to the Burgh Commissioners by Messrs. Crompton and Co., a deputation has been appointed to visit Edinburgh to obtain information on electric lighting matters.

Municipal Telephony.—The Belfast Law and Improvements committee are considering the advisability of establishing a municipal telephone exchange.

Municipal Trading.—The Association of Trade Protection Societies discussed the question of Municipal Trading at their annual meeting last week. A motion was submitted on behalf of the Leicester Society in condemnation of Municipal Trading, but Ald. Southern (Manchester) proposed an amendment to the effect that any enterprise requiring interference with public streets, such as gas, water, electricity, hydraulic power, or telephones, should be in the hands of municipalities, but that it was undesirable for municipalities to indulge in retail trade. After discussion the original resolution was withdrawn and the amendment was agreed to.

Palestine.—So far neither the electric light nor gas has been introduced into Palestine. Paraffin lighting affords the chief means of illumination, supplemented by a small supply of candles. Owing to the development of the orange-growing industry and the continued increase in the value of general exports, the wealth of Palestine is rapidly increasing.

Portsmouth.—An inquiry was held last week into the Corporation application to borrow £9,775 for electric lighting extensions. Ald. Ellis explained that the loan was required chiefly for main extensions. The demand for current was steadily increasing, and during the past year they had connected up the equivalent of 14,000 8 c.p. lamps. Technical evidence was given by the superintendent (Mr. E. Price). There was no opposition.

Railway Station Lighting in Germany.—The Rhenish-Westphalian Electricitäts Gesellschaft has secured a contract from the Prussian State Railway authorities for the electric lighting of all the railway stations in the Essen district.

Redcar.—A special meeting of the District Council was held last week to consider a proposal to erect electricity works. Mr. Eldridge, electrical engineer of the Tees Union Shipping Co., attended and advised the council to construct electric tramways in addition to supplying electric current for lighting. The joint scheme would, he said, undoubtedly prove remunerative. The consideration of the matter was adjourned.

Rosario (Argentina).—There is every probability that the tramway lines in this city will shortly be converted to electric traction, a joint stock undertaking with British capital having arranged with the present owners for the purchase of the lines. The Municipality have been asked to grant the company a concession, and upon the satisfactory completion of the negotiations in this matter depends the early conversion of the lines to electrical working.

St. Louis, Mo. (U.S.A.).—There are 450 miles of single track of electric and cable street railroads in this city, the greater portion of which is electric or is being converted to electric traction.

St. Martin-in-the-Fields (London).—The streets in this district, including the Strand, Haymarket, Trafalgar-square, and Leicester-square, are now lighted electrically. The annual cost of lighting the parish will be £1,362 for the first seven years, and £561 more than the present cost of gas thereafter. The illuminating power of the arc lamps is 79,000 c.p. more than the old gas lamps. Current is supplied by the Charing Cross and Strand Corporation.

Salford.—At the Corporation meeting on Friday a letter from Mr. C. L. Turner, borough electrical engineer, was read:—

Mr. Turner stated that he was unable to comply with the Council's request that he should resign his office, as he could not see any reason why he should resign. He knew that the charges brought against him were without foundation, and he considered that the evidence he produced to the Special committee was sufficient to disprove them. If the Council thought otherwise they must act accordingly.

The mayor (Ald. Rudman) then moved that in view of Mr. Turner's refusal to comply with the resolution of the Council requiring him to resign forthwith, the Council hereby determined his appointment and instructed the borough treasurer to pay Mr. Turner three months' salary in lieu of notice. Ald. Phillips seconded. Ald. Mandley did not think this action was quite judicious. Either Mr. Turner had been guilty of acts which justified the Council in dismissing him or he had not. If he had not done the things alleged against him the Council would be doing him a great injustice by turning him away in this manner. If he had done what had been charged against him it was an absurdity to give him three months' salary. Mr. Desquesnes thought it the best way out of the difficulty. If they dismissed Mr. Turner without notice or salary in lieu of notice they would render themselves liable to an action at law. It was, therefore, best to adopt the plan now recommended. Mr. G. H. Jones expressed his belief in Mr. Turner's innocence, and urged that in simple fairness they should give Mr. Turner the opportuity of clearing himself or justifying the Corporation's action in dismissing him. The resolution was adopted with three dissentients. Mr. Haworth subsequently made a personal statement in reply to a question.

The electric lighting accounts were presented at the Corporation meeting on Friday. There was a deficiency of £2,028 on the year's working, against £859 in 1898, an increase of £1,169 to be rated for this year. Of this increase about £800 was calculated to belong to the interest on loans and sinking fund and preliminary expenditure chargeable to revenue with respect to the new electricity station, &c. The Tramways committee, instead of estimating to hand over a sum of £591, estimated to require £2,014, making a total extra requirement of £2,605. This was necessitated by the provision required to

Digitized by Google

be made for loans to meet the expenditure now being incurred on new electric tramways.

Scarborough.—The Streets and Buildings committee have decided to obtain a report from a consulting engineer as to the construction of an electric tramway from the top of the North Cliff to Clarence Drive.

Sheffield District Railway.—On Monday the Duke of Portland opened the new Sheffield District Railway, part of an important new line running, or ultimately to run, from Attercliffe, Sheffield, to Sutton-on-Sea, Lincs. The Sheffield District Railway forms part of the Lancashire, Derbyshire, and East Coast Railway (known as the "Dukeries" route) which will join at Lincoln the Lincoln and East Coast Railway, which again joins up the Great Northern system on to Sutton-on-Sea, Lincs. This L.D. and E.C. line taps a very important district, and is not without interest in connection with the electric power bills now before Parliament. By the completion of the Sheffield District Railway a new main road between Sheffield and London is opened, and access is given to a district in which is situate some of the most famous historic homes of England. At Attercliffe a goods station of over 40 acres in extent has been erected in the immediate neighbourhood of many of the largest engineering firms of the country, including Hadfields, Vickers, Son and Maxim, John Brown and Co., Hawksleys, &c. Mr. H. Willmott, general manager of the L.D. and E.C. Railway is also general manager of the Sheffield District line. Mr. R. Elliott Cooper, chief engineer of the L.D. and E.C. Railway, and Mr. J. Wilson, of the Great Eastern Railway, have designed the works, which have been carried out under the supervision of Mr. E. O. Ferguson, resident engineer. The contractor is Mr. C. J. Wills, of London and Manchester.

Siam.—There are 26 rice mills at Bangkok, seven of which have independent electric lighting plants. The generating plant and apparatus is chiefly British. Another important industry of this district is the teak wood sawmills. Three of these mills are lighted electrically by independent plants of British manufacture. This is in addition to the old-established installation for lighting the city of Bangkok and for the supply of current for domestic purposes. The city has also two power stations for the electric tramway system, which has become firmly established in public favour in this comparatively up-to-date Asiatic city.

Surbiton.—A site for an electricity generating station has been purchased by the District Council.

Syra (Greece).—The public lighting of this town has been carried out by the Hellenic Electric Co., of Athens, an undertaking allied with the French Thomson-Houston Co. The Hellenic Co. is providing installations for public and private lighting in Athens, the Piræus, Patras, Calamata, and the Ionian Islands. The concession for Syra has been granted for 45 years by the municipality, who, for public lighting, have contracted for 200 16 c.p. and 200 10 c.p. incandescents and for a number of 500-c.p. arcs, at a total charge of £950 per annum at current exchange. The generating plant at the Syra station consists of Babcock and Wilcox boilers, Escher-Wyss engines and Thomson-Houston dynamos. The electric light is proving a serious rival to the acetylene gas undertaking established last year, the charge for electric current being about on a par with that charged for the acetylene gas lighting.

Telegraph Rates to India.—It is quite refreshing to record the proceedings at a meeting of the directors of the Glasgow Chamber of Commerce. Usually at meetings of Chambers of Commerce the subject of the reduction of telegraph rates is discussed without any regard to whether the drastic reductions recommended by members can or cannot possibly be made. At Glasgow, however, Mr. John Galloway was able to put the matter forcibly and logically before the directors when dealing with a draft memorial to be presented to the Postmaster-General on the subject of reduction of rates between this country and India. Mr. Galloway said he was in agreement with the committee in the desirability of securing a reduction in the telegraph rates to India. He objected, however, to endorsing the view of the Liverpool Chamber, quoted in the memorial, that the rate ought to be reduced from 4s. to 1s. a word. Before they could take such a position they would require to take into consideration the amount of capital involved in the laying down of telegraph cables, the amount of working expenses, the risks of breakage of cables, and the cost of upkeep. The Glasgow Chamber, he thought, would be placing themselves in an exceedingly wrong position if they were to endorse the view of the Liverpool Chamber. It would be sufficient to frame the memorial to the Postmaster-General in general terms. He further urged that it should not be taken for granted that the companies intended to maintain the present rate of 4s. per word. Official communications had been received from the Eastern Telegraph Co. by the Chamber stating that they were willing to reduce the rate to 2s. 6d. a word, even though the Government did nothing in the way of providing a subsidy. He thought that the memorial should be altered in these respects. Mr. W. F. G. Anderson asked why the companies had not made the reduction if they were willing to do it. Mr. Galloway said that negotiations had been going on for two years. Meantime the companies were waiting to see if the Government would meet them and help them to reduce it still further. It was agreed to adopt Mr. Galloway's suggestion and to frame a memorial in general terms.

Telegraphic Communication with Germany.—In the preamble of the bill laid before the German Federal Council for the laying of a fifth submarine telegraph cable from Germany to England, the following particulars are given regarding the steady increase of traffic. The number of telegrams amounted in 1895 to 1,867,868, and in 1899 to 2,465,613, an increase of 32 per cent, of which nearly 13 per cent. was in 1899 alone. In consequence, the lines are so overburdened that in commercial circles complaints are frequent, and Bremen especially claims better telegraphic communication with Liverpool, in the interests of the German cotton industry. The Bremen Cotton Exchange has had to make use of the roundabout and expensive route *viâ* New York to get its market telegrams from Liverpool, and has in this way received them two hours earlier than *via* London. The new cable of four conductors is to start from Borkum and end at Bacton.

Telephone at Manchester.—Ald. Southern has resigned the chairmanship of the Manchester Special Telephone committee. In the letter communicating his decision to resign, Ald. Southern states that he does so because he feels he will be able to do better service to the cause of cheap and efficient telephony by no longer remaining a member. He is of opinion that this cause would be best served by municipal exchanges within urban areas, the trunk lines being worked by the Post Office department, with free interchange of terminal facilities. But on this question Manchester is in a different position from any other town. The City Council had approved the application of a competing company for a licence within the Manchester area. It had been decided by the committee to purchase (if possible on reasonable terms) the Manchester exchange of the National Telephone Co., and that company had been asked whether it was willing to sell and upon what terms, it being the purpose of those who recommend this course to also recommend that any injustice done to the Mutual Co. should be recompensed by a pecuniary consideration. It appeared to him (Ald. Southern) that the National Co. could prolong the present state of things for almost any period they chose, and he regarded this as intolerably unfair alike to those citizens who were wishful for a more efficient and cheaper telephone service and to those who, encouraged by the attitude towards them of the Corporation, had incurred serious responsibilies in their efforts to supply a competing system affording those qualities of efficiency and cheapness which were desirable. This letter will come before the Council at its next meeting.

Telephonic Communication with the Continent.—The following communication has been received by the Secretary of the Association of Chambers of Commerce in the United Kingdom from the Postmaster-General:—

"The obstacle to the establishment of telephonic communication with countries other than France has consisted in the fact that it has not hitherto been found possible to devise a type of cable which would render conversation practicable across stretches of water much wider than the Straits of Dover. Various types of cables were devised and tested, and ultimately a cable, constructed on a new and apparently very promising principle, was laid between North Wales and Ireland, in the hope that the experience thus acquired would enable this Department to make practical proposals for telephonic cables to Belgium and the Netherlands Unfortunately, however, the experiment proved unsuccessful from a telephonic point of view; and, while the problem is still being closely studied, it cannot be said that a solution is in sight. In these circumstances, the Postmaster-General is unable to hold out the prospect of the establishment of telephonic communication with the Continent generally at an early date, but he will continue to give the matter his best attention, and meanwhile he is negotiating with the French and Belgian Administrations with a view to the establishment of a telephonic service through France to Brussels and Antwerp."

The Hague.—The Elektricitäts Actien-Gesellschaft Schuckert and Co., Nuremberg, have obtained the contract for the conversion of the local tramways to electric lines.

Trowbridge.—The Lighting committee have been requested to report upon the desirability of obtaining electric lighting powers.

Twickenham.—The Twickenham and Teddington Electric Lighting Co. have obtained a provisional order for this district.

Watford.—The demand for electric current is so great that the electrical engineer (Mr. W. H. Colebrook) has been directed to inquire as to whether secondhand or other supplemental plant can be obtained to meet the extra supply through the winter, and to report how long it will take to obtain permanent plant. In view of the absolute necessity for the provision of additional plant, a resolution, passed in October last, that no further extension of mains be carried out until the Council have completed all the works in hand, has been rescinded.

Yeadon.—The Board of Trade has been asked to extend the time for complying with the Yeadon provisional order, obtained in 1894, and the Leeds Council have been asked for terms for supplying electricity in bulk for lighting and traction in the district.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

Durban (Natal) Corporation invite tenders for (*a*) the supply, delivery and erection of the overhead equipment for about 16 miles of equivalent single track, including poles, overhead trolley wire, distribution boxes, &c. ; (*b*) the supply, delivery and erection of 22 double-deck motor cars complete ; (*c*) the supply and erection of electricity generating plant, including three 250 kw. direct-coupled generators, boilers, condensers, cooling tower, switchboard, &c. Further particulars are set out in an advertisement, and specifications may be obtained from the agents to the Corporation (Messrs. Webster, Steel and Co.), 5, East India-avenue, Leadenhall-street, London, E.C., after 29th inst. Tenders in duplicate must be delivered to the agents by June 29, or to the town clerk of Durban by mail delivery on or about Monday, July 23.

South London Electric Supply Corporation invite tenders for a complete installation of 3,000 lights on the premises of 500 consumers in any part of the company's area of supply, and also for the installation of two arc lights on the premises of any consumer in the same area. Specifications may be obtained from the secretary (Mr. H. H. Boyer), 54, Bengeworth-road, Loughborough Junction, London, S.E., and tenders must be in by Saturday, June 2. See advertisement.

Dundee Town Council require tenders for the overhead equipment of four electric tramway routes particulars of which are set out in an advertisement. Specifications, &c., may be obtained from the city electrical engineer (Mr. Walter H. Tittensor), and tenders must be lodged with the town clerk (Sir Thomas Thornton, LL. D.), City Chambers, Dundee, by 31st inst.

Dundee Gas Commissioners invite tenders for small coal and electricity meters. Specifications from the city electrical engineer (Mr. Walter H. Tittensor), Dudhope Crescent-road, and tenders must be delivered to the town clerk (Sir Thomas Thornton, LL.D.), City Chambers, Dundee, by 31st inst. See advertisement.

Sutton Coldfield Corporation invite tenders for the supply and erection of electricity generating plant, particulars of which are set out in an advertisement. Specification may be obtained (after 24th inst.) at the offices of the town clerk (Mr. Thos. V. Holbeche). The contracts will be carried out in accordance with the plans and specification of the consulting engineer (Mr. W. C. C. Hawtayne), 9, Queen-street-place, London, E C, from whom further information can be obtained after 24th inst. Tenders must be delivered to Mr. Holbeche before noon of June 21.

Manchester Tramways committee invite tenders for the overhead equipment of three tramway routes. Specification may be obtained from the general manager (Mr. J. M. McElroy), tramways department, Town Hall, Manchester, and tenders (addressed to chairman) must be in by June 9. See also advertisement.

Bootle Corporation invite tenders for supply and laying of underground electric cables, erection of arc lamps, and the supply of mechanical stokers. An advertisement contains further particulars, and specifications may be obtained from the borough electrical engineer (Mr. W. R. Wright). Tenders to the town clerk (Mr. J. Henry Farmer) before June 16.

Chester Corporation invite tenders for steam, exhaust, feed-suction, condensing water pipes and valves. An advertisement gives further particulars, and the specification may be obtained from the city electrical engineer (Mr. F. Thursfield). Tenders to town clerk (Mr. S. Smith) by 10 a.m. of June 4.

North-Eastern Railway Co. invite tenders for telegraph apparatus, telegraph wire, and line stores. Forms of tender can be obtained from Mr. A. Graves, telegraph department, York, and tenders must be sent to the secretary (Mr. C. N. Wilkinson), York, by June 4. See advertisement.

St. Pancras (London) Vestry invite tenders for re-arranging and making additions to bare copper strip conductors. Specification may be obtained at the offices of the Electricity department, 57, Pratt-street, N.W., and tenders must be sent to the vestry clerk (Mr. C. H. F. Barrett) by noon on Friday, June 7. An advertisement contains further particulars.

Bradford Corporation require tenders for the supply and erection of a switchboard, or for alterations to existing switchboard, at the Valley-road electricity works. Specification can be obtained from the city electrical engineer (Mr. R A. Chattock), Town Hall, and tenders must be sent to the town clerk (Mr. Frederick Stevens), by June 7. An advertisement contains additional particulars.

Bradford Corporation require tenders for coal-conveying apparatus, hoppers and ash-conveying apparatus for their Valley-road electricity works. Tenders to town clerk (Mr. Frederick Stevens) by 31st inst.

Corporation of *London* Streets committee invite tenders for the supply on hire of electrically-driven dust carts. Tenders to town clerk (Sir John B. Monckton), Guildhall, E.C., by June 1. See advertisement.

Messrs. Andrew Barclay, Sons and Co. (Ltd.), Caledonia Works, Kilmarnock, require tenders for a 60 kw. (or 80 kw.) dynamo. Tenders by Wednesday, 30th inst. See advertisement.

Sleaford Council invite tenders for electric lighting plant. Tenders to clerk by June 12.

Ealing District Council invite tenders for a storage battery and a steam alternator. Tenders to clerk by June 11.

The Provost, Magistrates, and Commissioners of the burgh of *Partick* invite tenders for the construction, supply, and erection of a dust destructor, with furnaces, flues, water-tube boilers, economiser, fans, and forced-draught furnaces. Tenders to Mr. Jas. Donaldson, town clerk, 97, West Regent-street, Glasgow, by noon of June 8.

Leeds Lighting committee invite tenders for two or three 630 kw. two-phase generators and one or two sets of surface condensing plant. Tenders to town clerk (Mr. W. J. Jeeves) by 10 a.m. of 28th inst.

Great Grimsby Corporation invite tenders for the supply and delivery of arc lamp posts and brackets. Tenders to town clerk (Mr. W. Grange), St. Mary's Gate, Grimsby, by June 1.

Great Grimsby Corporation also invite tenders for the supply and delivery of electricity meters. Tenders to Mr. Grange by June 1.

Newcastle-upon-Tyne Tramways committee invite tenders for pumping apparatus. Tenders to town clerk (Mr. Hill Motum) by June 1.

Fulham (London) Vestry require tenders for the wiring of their electric lighting works. Tenders to Mr. W. J. H. Denselow, clerk, Town Hall, Walham Green, S.W., by June 4.

London County Council's Asylums committee invite tenders for the installation of electric lighting and power (except generating plant) and the installation of telephones, tell-tale clocks, fire alarms and call bells at the Horton Asylum, near Epsom, Surrey. Tenders to the committee, 6, Waterloo-place, S.W., by 10 a.m , June 16.

Walthamstow District Council invite tenders for the supply and erection of arc lamp posts and accessories and glow lamps on posts and on existing gas standards. Tenders to clerk (Mr. E. J. Gowen), Town Hall, Walthamstow, by 5 p.m. 29th inst.

Southampton Corporation invite tenders for a water-tube boiler with steam and other pipes and sundry ironwork. Tenders to town clerk (Mr. R. R. Linthorne) by 28th inst.

Bridgwater Town Council invite tenders for the supply and erection of electricity generating plant. Tenders to town clerk (Mr. W. T. Baker) before 3 p.m. on June 7th.

Glasgow Corporation invite tenders for the supply of two sets of switchboards and instruments for 4,000 amperes each. Tenders to town clerk (Sir J. D. Marwick) before10 a.m., June 12.

Wolverhampton Tramways committee invite tenders for the construction of nearly two miles of tramway. Tenders by June 26.

Tenders are invited for wiring the *Leeds* Central Fire Station. Tenders to town clerk by 28th inst.

Heywood Council invite tenders for the erection of electricity station buildings. Tenders by 28th inst.

Luton Town Council require tenders for the erection of electricity station buildings. Tenders by June 18.

Swedish Telegraph Administration invite tenders until 28th inst. for 10,000 metres of copper wire.

Alexandria (Egypt) Harbour Authorities invite tenders until July 1 for supply and erection of electric lighting plant at Port Said harbour.

Tenders are invited until June 4 by the municipal authorities of *Fuente de Cantos* (Badajoz, Spain), for the electric lighting concession for 20 years. Tenders to el Secretario del Ayuntamiento.

TENDERS RECEIVED AND ACCEPTED.

Walsall County Council have accepted the tender of the Electrical Power Storage Co. for repairing and renewing the storage battery at the St. George's Hill transformer station for £495, and that of Mr. A. Lynex for engine and boiler foundations for £190. 15s.

Barnes District Council have accepted the tender of Messrs. G. Munday and Sons for the erection of electricity station buildings at £5,719.

Kingston-on-Thames Town Council have accepted the tender of Mr. T. Robinson for foundations for new steam alternator at £150.

Hertfordshire County Council have accepted the tender of Messrs. Hayward Tyler and Co. for the electric lighting of the Isolation Hospital at the Hill End Lunatic Asylum for £254. 13s. 6d.

Walthamstow District Council have accepted the tender of the W. T. Henley's Co. for supplying and laying mains and cables at £10,658. 18s. 6d.

Digitized by Google

Subject to approval of the Local Government Board, the Visiting committee of the Northumberland Lunatic Asylum have accepted the tender of Messrs. McAulay, Clark and McLaren, Glasgow, for the electric lighting of the asylum to the specification of Mr. A. A. Campbell Swinton. Thirty-one tenders were received.

The Bermondsey (London) Vestry have accepted the tender of Messrs. Hughes and Stirling for the erection of the chimney shaft at the electric light and refuse destructor works for £2,581. The tender of the same firm was recently accepted by the Vestry for the refuse destructor and boilers.

APPOINTMENTS VACANT AND FILLED.

An assistant lecturer and demonstrator in electrical engineering is required for the University College of North Wales, Bangor. Applications to the secretary and registrar (Mr. J. Lloyd, M.A.), not later than June 9. See advertisement.

A head-master is required for the Industrial School, Lucknow, India. Some additional information is given in an advertisement. Forms of application and further particulars can be obtained from the Director-General of Stores, India Office, Whitehall, London, S.W.

Brighton Corporation require an engineer in connection with their proposed electric tramway scheme. An advertisement contains further particulars, and applications must reach the town clerk (Mr. F. J. Tillstone), Town Hall, Brighton, before 10 a.m. on June 8.

The Belfast Electric committee require an engineer-in-charge and a junior assistant for their electricity works. Applications to city electrical engineer (Mr. Victor A. H. McCowen) by June 5. See advertisement.

The engineer to the Bury electricity works (Mr. S. J. Watson) has a vacancy for an improver. See advertisement.

A shift engineer and an engine driver are wanted at the Stafford electricity works. Applications to manager (Mr. J. F. Bell). See advertisement.

There is a vacancy for an improver at the Dundee electric light and traction station, of which particulars will be found in an advertisement elsewhere.

Johnson and Phillips' Electric Cable Works, Old Charlton, Kent, require a draughtsman and a shop foreman for their additional lead-covering cable factories. Particulars will be found in an advertisement on another page.

Southport Corporation require a manager for their tramways. Applications to town clerk (Mr. J. Ernest Jarratt), Town Hall, Southport, by 28th inst.

An assistant engineer is wanted at the Shrewsbury electricity works. Applications to town clerk by 31st inst.

Cardiff Corporation invite applications for the appointment of a tramways electrical engineer, at a commencing salary of £500 per annum. Applications to Mr. J. L. Wheatley, Town Hall, Cardiff, by June 1.

There is a vacancy for an assistant superintendent in the telegraph department of the Government of India. Further particulars may be obtained on application to the India Office, and applications should be sent to the Secretary, Public Works Department, India Office, Whitehall, London, S.W., by June 30.

Mr. Robert Maclean, local manager of the National Telephone Co., at Cardiff, has been appointed local manager to the State of Guernsey telephone exchange.

Mr. J. L. Chambers, engineer of the National Telephone Co., at Nottingham, has been appointed outside superintendent to the Glasgow Corporation telephone exchange.

Mr. G. S. Maben, assistant electrical engineer to the Belfast Corporation, has been selected for the post of chief assistant to the superintendent engineer at Bradford Corporation electricity works. The appointment is subject to ratification by the Council.

BUSINESS NOTICES.

Messrs. John Webster and Joshua Ellis (trading as Webster and Co.), electrical engineers, Queen's Arcade, Leeds, have dissolved partnership. Debts by Mr. Webster, who continues under the old title.

Messrs. A. W. Isenthal and C. P. F. M. Potzler, trading as Isenthal, Potzler and Co., electrical engineers, &c., 85, Mortimer-street, London, W., have dissolved partnership. Debts by Mr. Isenthal, who continues as Isenthal and Co.

Messrs. Johnson and Phillips' Electric Cable Works, ask us to state that Mr. T. M. Harvey left their employ on 19th inst.

Messrs. Browett, Lindley and Co. (1899) (Ltd.) have opened London offices at 6, Old Queen-street, Westminster, S.W. Mr. Thos. Browett, joint managing director, is in charge of the London office.

BANKRUPTCIES, LIQUIDATIONS, &c.

The Universal Electrical Advertising Syndicate (Ltd.) is to be wound up voluntarily, and Mr. T. G. Mellors, King John's Chambers, Nottingham, is liquidator.

A second and final dividend (9½d.) will be payable on 30th inst. or any subsequent Wednesday, between ten and one, at Messrs. Pratt, Norton and Co.'s, 9, Old Jewry-chambers, E.C., in the failure of S. G. Trehearne and A. H. Crump (trading as Trehearne, Son and Crump), electrical engineers, &c., 155, Fenchurch-street, London, E.C.

Winding-up Petition.—A petition for the winding-up of the River Plate Electric Light and Traction Co. (Ltd.), will be heard in the High Court on 30th inst.

Businesses for Disposal.—An electric lighting business in a town on the north-east coast is advertised for sale in another column.

An electrical engineering business is advertised for sale in another column. The works are conveniently situated within 10 minutes of London.

For Sale.—A leasehold factory and about four acres of land, situated in Essex, and about 12 miles from London, together with tools and plant and surplus stock, are offered for sale by private tender. Further particulars are set out in an advertisement. Tenders must be sent (by June 19) to Messrs. Sydney Lee, and Co. (Ltd.), 9, Furnival-street, Holborn, London, E.C., from whom forms of tender and conditions of sale may be obtained.

"Simplex" Steel Conduit System.—A neat pamphlet setting out a list of some of the more important electric lighting installations where the Simplex Steel Conduit Co.'s system has been adopted during 1898-1900 is issued, and gives some idea of the extent to which this company's system has been employed in work of a very varying character. The pamphlet chiefly consists of testimonials from those who have installed and those who have used these fittings, and are all of a very satisfactory character.

Electrical Accessories Catalogue.—Messrs. D. H. Bonnella and Son (Ltd.), of 58 and 60, Mortimer-street, London, W., have just issued a useful price list of electric bells and accessories, and sections L and T of their main catalogue of electric light accessories and telephones and accessories respectively. These lists are very fully illustrated, and can be profitably consulted for a large variety of apparatus and sundries for use in electric lighting work, medical electricity, domestic appliances, telephone installations (public and private), &c. Messrs. Bonnella and Son are actual makers, and have old-established works at 43, Kirby-street, Hatton-garden, London.

Telephone and Bell Catalogue.—We have received from the International Electric Co., 55, Redcross-street, E.C., a copy of the fourteenth edition of their catalogue of bell and telephone material. The firm makes a speciality of this class of supplies, and the new edition includes almost every conceivable piece of apparatus from the ordinary push and "baby" bell to multiple telephone switchboards. At the end of the book is an excellent collection of diagrams showing how the various apparatus should be connected.

Westinghouse Plant.—The British Westinghouse Co.'s circular No. 1,027 deals with the Westinghouse incandescent street lighting system, and illustrates the street light shunt coil. Claim is made that the entire system operates with high efficiency, and that the percentage of current required to keep the shunt coils magnetised is very small.

B. T. H. Plant.—Pamphlet No. 63 issued by the British Thomson-Houston Co. describes and illustrates direct-connected continuous-current lighting generators. The L type form of generator is dealt with. Pamphlet No. 64 describes this company's alternating current fan motor, of which several sizes are illustrated.

Dick, Kerr and Co.'s Plant—Circulars Nos. 102 and 103, issued by Messrs. Dick, Kerr and Co. (Ltd.), treat of "Top-seat, single-deck motor cars" and "New rolling stock for the Waterloo and City Railway" respectively. Both pamphlets are well illustrated, No. 102 showing some excellent examples of cars as used on the Liverpool, Bolton, Potteries, Blackpool and Fleetwood, and other lines.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from May 16 to May 22, with the ports of destination:—

Africa—Alexandria, £35; Cape Town, £4,374 (including £4,103 telegraph material); Chinde, £864 (telegraph material); Durban, £245; East London, £9. *Argentina*—Buenos Ayres, £860. *Australasia*—Christchurch, £11; Lyttleton, £145; Melbourne, £580; Sydney, £514; Wellington, £568 (including £500 telegraph cable). *Azores*—£330,625 (telegraph material and apparatus). *Brazil*—Rio Janeiro, £1,487 (telegraph material). *Canada*—Halifax, £51 (telegraph paper); Montreal, £80. *Ceylon*—Colombo, £10. *Colombia*—Santos, £199 (telegraph material). *France*—Rouen, £50. *Germany*—Hamburg, £335 (telegraph material). *Holland*—Amsterdam, £300; Rotterdam, £45. *Hong Kong*, £21. *India*—Bombay, £40; Calcutta, £216. *Russia*—Riga, £64 (telegraph material); St. Petersburg, £41. *Siam*—Bangkok, £85. *Spain*—Bilbao, £1,330 (telegraph cable); Mazagan, £80; Vigo, £179 (telegraph apparatus). *Straits Settlements*—Singapore, £170 (including £65 telegraph material). Total £343,550 against £11,076 for eight days last year (May 17 to May 24).

Digitized by Google

COMPANIES' MEETINGS AND REPORTS.

British Aluminium Co. (Ltd.).

The fifth ordinary general meeting was held yesterday, Mr. R. W. WALLACE, Q.C., presiding.

The CHAIRMAN said that a few years ago aluminium was a curiosity, but it had now become one of the most useful metals in the arts. It had been difficult for the company's travellers to induce manufacturers to use aluminium as fast as the directors would like. During the 2½ years the company had been in a dividend-earning capacity they had had 14,000 different orders. Most of these, however, were only for small quantities of metal for trial purposes. So far the company had not derived any great financial benefit from Government orders. In Germany half the output of the Neubasen Co. went to the Government, and he had no doubt that, in a short time, the same state of things would prevail in this country. Aluminium had been utilised for the balloon equipment in South Africa, and the metal had also been utilised in connection with the field telegraph and field telephone. The Boers had been before us in this matter. A considerable quantity of aluminium was ordered by them from Germany, and had found its way into their equipments. In the navy more had been done as regarded the use of this metal. After complaining that the railway companies insisted on treating aluminium as a precious metal, and charging for its tariff accordingly, he said that so far the company had earned 20 per cent. of the 35 per cent. due to December 31 on the cumulative preference shares. They had been working more for the future than for the present.

Lord KELVIN said that if the same rate of progress that had been made was continued a very great future in the way of practical success would be secured to the company. The question of water-power, in which they were so largely interested, was one of supreme importance now in view of the great increase in the price of coal. The price of coal would it was hoped fall somewhat before long, but that it must go on increasing on the whole from year to year seemed quite certain, when it was considered that the total quantity of coal all over the world was limited.

The directors' report was adopted.

It was afterwards agreed to increase the capital to £400,000 by the creation of 10,000 new cumulative preference shares of £10 each, to rank for dividend in priority to the existing preference shares. Only 5,000 of the new shares will at present be issued.

Callender's Cable and Construction Co. (Ltd.).

The fourth annual general meeting was held yesterday (Thursday) under the presidency of Mr. HENRY DRAKE.

The SECRETARY (Mr. H. A. Manning) having read the notice calling the meeting,

The CHAIRMAN said he hoped the shareholders would consider the statement submitted by the directors satisfactory in view of the difficulties against which the company had had to contend during the past year. There had been a rise in the price of practically all the materials used at the factory, and in the opinion of the directors the result produced reflected great credit on the skill and ability of their managing director. Dealing with the balance-sheet, he said the buildings, machinery and plant now stood—after allowing £5,000 written off for depreciation this year—at £183,000, against £135,000 in the previous balance-sheet. This had been necessitated by the increase in the business. The item of cable-drums stood at £9,800, against £4,800 a year ago, and this increase was also owing to the expansion of the business. The stock in hand amounted to £69,000, against £43,000. The item of "expenditure on contracts in course of execution, including materials and plant," figured for £68,000, against £42,000, and sundry debtors at £290,000, against £172,000. The cash was £11,000, against £21,000, and shares in other companies amounted to £7,500, against £5,000. The directors always endeavoured to keep this item down as low as possible, but now and again they were obliged to take a few shares in order to secure contracts. On the other side the only important items were bills payable £142,955, and trade creditors and other liabilities £80,000 (together £223,000), compared with £119,000 in the previous balance-sheet. Sundry debtors, on the other side of the account, showed an increase of £118,000. In the profit and loss account, the manufacturing profit appeared at £64,000 against £59,000; and after paying all expenses, including the repair and maintenance of the plant and the removal of the machinery to the new factory, a balance was carried down of £41,966, out of which interest on debentures, dividend on preference shares, and interest on new ordinary shares had been paid; £5,000 had been appropriated to depreciation of plant and machinery, and a balance was left of £33,221. Out of this the directors propose to pay a dividend to the holders of the original ordinary shares at the rate of 10 per cent. per annum, clear of tax, or 10s. per share, and a bonus of 5s. a share; and after adding £10,000 to reserve, £8,221 would remain to be carried forward. The reserve fund, with this addition, would stand at £73,881, which was a very satisfactory figure; and the return upon the ordinary shares would be 15 per cent., or the same as was paid in 1898. With reference to the issue of new preference shares, the company's business had increased very largely. Last year the directors issued 10,000 ordinary shares of £5 each at a premium of £5 a share, producing £100,000, and the shareholders might naturally suppose that this would have lasted a considerable time. He would, however, show them where the amount had gone. The increase in the property had been £47,000, on cable drums £5,000, on stock £26,000, in expenditure on contracts £26,000, and in debentures £118,000. These items amounted together to £222,000. On the other hand, there had been a diminution in the cash of £10,000, and the increase in the item of creditors was £104,000, being together £114,000, and leaving a balance of £108,000. They were, therefore, in this way really at the present time £8,000 worse off than they were a year ago. The issue of the new preference shares would be made as soon as the arrangements could be completed, and would be offered *pro rata* to the existing ordinary and preference shareholders. He moved the adoption of the report and balance-sheet.

Lieut.-Col. G. A. ELLIOTT seconded the motion, which was carried unanimously, and the dividend and bonus mentioned were afterwards approved.

Mr. T. O. CALLENDER endorsed the remarks of the Chairman as to the difficulties they had had to contend with during the year, and said that they had had more than their share of the work that was going, and had no reason to complain of the prices obtained under their contracts. They had over 150 contracts in hand, and several of their departments had to be run day and night. He thought the prospects of the company for a continuance of the good business they were at present having were favourable, and he believed that 1900 would turn out to be another excellent year.

A vote of thanks terminated the proceedings.

West India and Panama Telegraph Co. (Ltd.)

The report of the directors for the half-year ended December 31st last states that the amount to credit of revenue is £22,643. 14s. 7d., against £51,937. 16s. 7d. for the corresponding half-year of 1898, and the expenses have been £21,432. 13s. 3d. against £24,443. 15s. 6d., leaving a balance of £1,211. 1s. 4d. The revenue for the corresponding period of 1898 was abnormally large in consequence of the Spanish-American war. Since the conclusion of the war the traffic has resumed its normal character, and owing to its being carried at lower rates than formerly, and there being no compensating increase of business, the company is now feeling the full effects of the reductions made in the message tariffs. Notwithstanding the reduced rates, coupled with the efforts which it was understood Her Majesty's Government were making to stimulate the trade and enterprise of the West Indies, the result of the half-year's working is most discouraging. To this amount of £1,211. 1s. 4d. there is to be added £3,021. 8s. 2d. interest on investments, which has been credited to revenue instead of to reserve as heretofore, making, with £379. 14s. 2d. brought forward, £4,612. 3s. 8d. to credit of revenue. As it requires £11,769. 12s. to pay the half-yearly dividends on the first and second preference shares, the amount available is insufficient by £7,157. 8s. 4d. The directors, therefore, recommend the payment of dividends by drawing on the reserve fund, and also that a dividend of 1s. per share (free of tax) be paid on the ordinary shares. £12,000 has consequently been transferred from reserve, leaving £279. 6s. 8d. to be carried forward.

Notwithstanding the reductions of tariff made by the company, the colony of Barbados has reduced its subsidy from £2,500 to £1,500 for the current year. The directors regretfully express the opinion that low rates for West Indian telegraphic communications cannot be maintained without the financial assistance of the Government. In view of the discouraging circumstances they have, therefore, recently addressed the Secretary of State for the Colonies, pointing out the present position of the company and asking for Imperial aid, without which, it appears to the board, the maintenance of the telegraphic communications of the West Indies, in the interests of commerce of Her Majesty's Government and the Colonies, will be imperilled. A reply from the Colonial Office is anxiously awaited.

Castner-Kellner Alkali Co. (Ltd.).

The report of the directors for the year to March 31, 1900, states that the result of the trading is a gross profit of £59,486. 13s. 5d., out of which £11,273. 6s. 7d. has been expended in repairs, renewals and special improvements of the working plant, which is in a very efficient condition. The net profit is £45,398. 7s. 3d., which, with £5,341. 17s. 1d. brought forward, makes £50,740. 4s. 4d. An interim dividend at the rate of 8 per cent. per annum has been paid for the six months to Sept. 30 last, amounting to £12,000, and debenture and loan interest £6,694. 9s. 2d. has been paid, leaving an available balance of £32,045. 15s. 2d. The directors recommend a further dividend at the rate of 8 per cent. per annum for the six months to March 31, and to write off £6,277. 17s. 6d., the expenses of the debenture issue; to appropriate £10,000 to depreciation reserve; and to carry forward £3,767. 17s. 8d.

The company's process is working very satisfactorily, and experience has enabled it to be improved in important features which strengthen the position of the company, apart from the protection afforded by the patents.

CALCUTTA ELECTRIC SUPPLY CORPORATION (LTD.)—In moving the adoption of the directors' report at the annual meeting recently, the chairman (Col. A. J Filgate) said the company's progress at first was slow. Owing to various difficulties, chiefly in getting material from England, they could not get their mains laid so fast as they had intended. They were not able to find room for overhead mains in some of the streets occupied by the Government telegraph and telephone wires, and had to change the proposed routes or to place the mains underground. From the date of starting the works to Dec. 31 they had sold 54,897 units of current, but from Jan. 1 to 13th ult. they had sold 74,673 units. The municipality had not yet come to any decision in regard to public lighting, but the matter was under consideration, as was also the question of lighting Fort William. A great demand for electrically-propelled fans had sprung up. The large

Digitized by Google

difference which occurred in the sale of electric current between the winter and summer months in the case of electricity undertakings in Great Britain would not occur in Calcutta; indeed, it seemed probable that when the supply of fans came up to the demand the sale of current during summer would equal, if not exceed, that of the winter. The greater proportion of their consumers were located in the European quarter of the city, but they had a demand from native gentlemen, and they would have to keep on extending their mains to a considerable extent within the area of their original concession. They would soon have to provide additional generating plant, and either to increase the size of their station or to construct another in a different locality. The total commitments of the company at present amounted to about £108,000. As the directors contemplated further expenditure at an early date to deal with the extended area and to meet the increasing demand, they had decided to ask the shareholders to sanction an increase of capital from £100,000 to £200,000. Their licence had been extended to 42 years, the municipality having the right to purchase at the end of the 42 years, and at intervals of 10 years thereafter, at its then existing value, and the company were to pay a rent of one rupee a year for every pole erected in Calcutta. As there seemed a probability that a demand for electricity in other large cities and towns in India would shortly arise, the board had commenced negotiations in some quarters with a view of extending the scope of the company's operations. The report was adopted and a resolution passed increasing the capital of the company by the issue of 20,000 additional £5 shares, the new shares to be issued at such times and on such terms and conditions as the directors might think fit.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL CO. (LTD.)—The annual meeting of this company was held recently when the chairman (Mr. J. MacFarlan) said that during the year they had issued £15,000 debenture stock in order to provide for the increased value of the copper stock of the "Metall" Co. caused by the great rise in the price of raw material, and to carry out further extensions at the factory to cope with the greatly increased demand for the products of the company. They also issued preference shares, bringing the total amount to £50,000. Mr. Preschlin, the manager in Germany, had invented a joint for high-pressure copper tubes, and a considerable amount had been expended in testing the joint, in order to prove its value to the Board of Trade in England. These tests, by Messrs. D. Kirkaldy and Co., had given most satisfactory results, and they were now engaged in putting the joint before users in England. They had hoped that the result of the past year would have been sufficiently good to enable them to convert their 8 per cent. debenture stock into 5½ or 6 per cent. stock, but as things had turned out, they would not be justified in making the experiment. The "Metall" Co. had expended £3,500 on additions to land, buildings and water power, and £6,000 was expended on machinery, tools and factory appliances. Unfortunately the great demand in Germany for engineering goods precluded the delivery, until late in the summer, of certain parts which had to be made on the spot, and so they did not obtain the power they anticipated during the dry season. During the year, the sales showed a considerable increase, but both wages and stores increased out of proportion to the trade done. It was estimated that the trading profit would amount to over £21,000 whereas it amounted to £18,200 only. The working of the past year had, notwithstanding the difficulties encountered, given considerable cause for congratulation. The contract with the German Government expired in March last and had been continued for another year at the same prices, and they had all the principal users of copper goods on their books. The actual profit made in 1898 by the "Metall" Co. was £5,193, and in 1899 £6,310, and the current year's working should show a much better profit. They were exhibiting at the Paris Exhibition. It was not at first intended to do so, but they were approached by the Government, who stated that they would be prepared to pay the cost of the site, &c., and that it was their wish that the company should exhibit if possible. The dividend of 3¾ per cent. on the preference shares for the past year was then approved

NEW COMPANIES, STATUTORY RETURNS, &c.

BABCOCK AND WILCOX (LTD.)—This company was registered on April 30, with a capital of £630,000 in £1 shares, to acquire the business of Babcock and Wilcox (Ltd.), and to develop and extend the same, to construct, maintain, and work rail and tram roads, to carry on general business of an electric light and power company, &c. The first directors are J. Dewrance, A. T. Simpson, Sir W. Arrol, W. J. P. Moore, C. A. Knight, J. H. Rosenthal, and F. G. Biurne.

INGLETON WATER POWER CO. (LTD.)—This company was registered on May 14, with a capital of £7,000 in £1 shares, to take over the business of the Ingleton Carbide Co., and to carry on the business of calcium carbide manufacturers, &c.

INTERNATIONAL ELECTRIC TRACTION AND POWER SYNDICATE (LTD.)—This company was registered on May 16, with a capital of £25,000 in £10 shares, to carry on the business of railway and other waggon, carriage, and vehicle manufacturers, electrical and mechanical engineers, suppliers of electricity for motive power and other purposes, &c. The subscribers are R. Le Neve Foster, T. Pollock (engineer), J. P. Bedson, M.I.C.E., W. G. Rhodes, M.I.E.E., C. J. Hall, R. D. Cohen, and T. Harris.

McALPINE'S ELECTRICAL CO. (LTD.)—This company was registered in Edinburgh on May 13, with a capital of £5,000 in £10 shares, to take over the business carried on by H. McAlpine and Co., at 248, Hope-street, Glasgow, and to carry on the business of electrical engineers, &c. The subscribers are:—H. McAlpine, electrical engineer; John Dewar, electrical engineer; J. Paterson, A. McOnish, J. Dewar, printer; A. Macallan, J. Findlay. The first directors are:—Hugh McAlpine and John Dewar.

MIDLAND ELECTRIC CORPORATION (1900) (LTD.)—This company was registered on May 15, with a capital of £200,000 in £1 shares, to enter into an agreement with the British Insulated Wire Co. (Ltd.), to promote the development of the business of the Midland Electric Corporation for Power Distribution (Ltd.), and to carry on the business of electricians, electrical and general engineers, suppliers of electricity for the purposes of light, heat, and motive power, &c. The subscribers are W. M. M. Forwood, A. E. Haptie, C. O. Grindrod, F. W. Lintern, T. M. Watters, J. A. Bland, and E. R. Williams.

MONARCH MOTOR CO. (LTD.)—This company was registered on May 10, with a capital of £250,000 in £1 shares, to carry on business as electricians and electrical engineers, as importers and exporters, manufacturers of and dealers in motors, &c.

NORTH WALES AND DISTRICT LIGHT RAILWAY AND ELECTRIC POWER SYNDICATE (LTD.)—This company was registered on May 2, with a capital of £1,200, in £100 shares, to carry on the business of electrical and general engineers and the business of an electric traction company; to supply electricity for light, heat, and power, and to equip and maintain telephone and telegraph systems, railways, tramways, &c. The subscribers are J. Wolstenholme, J. Royle, E. Hague, F. F. Bennett (engineer), W. T. Pressland (engineer), W. H. Davies, and B. D. Beever.

ST. STEPHEN'S ELECTRICAL SYNDICATE (LTD.)—This company was registered on April 30, with a capital of £8,000, in £1 shares, to acquire the business carried on by Mr. J. E. Taylor at Shepherd's Bush, and to carry on the business of electrical, hydraulic, and general engineers, &c. The subscribers are E. Buchholtz (electrical engineer), J. E. Taylor (electrical engineer), E. S. Templeton (civil engineer), H. G. Well (engineer), G. Richberg (engineer), W. J. Chapman (engineer), and F. Smith.

CITY NOTES.

MEMORANDA.—Bank rate 3½ per cent. (May 24, 1900). Price of silver 27 11/16d. per oz. (May 24). Consols (2¾ per cent.) 101¼—101⅜ for money, 101 7/16—101 7/16 for account; 2½ per cent. 98¼—98½ (May 24). Stock Exchange Settling Day: Consols, June 1; Stocks and Shares Continuation Days, May 29 and June 12; Ticket Days, May 30 and June 13; Pay Days, May 31 and June 14; Mining Share Carry-over Days, May 28 and June 11.

BRITISH ELECTRIC PLANT CO. (LTD.)—Subscriptions have been invited this week to an issue of £75,000 in shares of £10 each in this company, which has been formed with a capital of £100,000. The managing director is Mr. Wilfred L. Spence, and the registered offices of the company 154, St. Vincent-street, Glasgow. The company is formed to carry on works in Scotland for the manufacture of electrical engineering plant of all kinds, and to carry on an electricity bulk supply business worked in conjunction with its own electric lighting and power plant. It is claimed that the district in which the company's operations will be conducted affords exceptional opportunities for the purposes of the company, which holds a provisional contract with the Alloa Commissioners for the supply of electric current in bulk for lighting and other purposes for 14 years, and thereafter for successive periods of seven years. It is stated that the directors of the company, all practical men, have subscribed for one-third of the present issue of shares; that no promotion money is paid; that there are no vendor's shares; and that none of the shares will be underwritten. The agreements entered into are all fully set out in the prospectus, and there is no waiver clause. The list closed on the 23rd inst.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION (LTD.)—At a meeting last week the resolutions increasing the capital (*see* our issue of 27th ult.) were confirmed.

HAMPSTEAD ELECTRIC SUPPLY CO. (LTD.)—Investors are again cautioned against responding to the invitation of Sims, Newman and Co., a firm of stock and share pushers who are hawking the shares of the above company, and informing all and sundry that the prospects for these shares are favourable. It will be remembered that at the last meeting of the company the dividend on the 5 per cent. cumulative preference shares was passed, and of course no dividend was paid on the ordinary shares. The shares, both preference and ordinary, may well be left to local purchasers, who are best acquainted with the outlook for this "investment."

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER CO. (LTD.)—Messrs. Turquand, Youngs and Co. have issued their report on the financial position of this company. They are of opinion that since 1894 dividends, amounting to £15,645, have been paid otherwise than out of profits. Various items debited to capital should properly be charged to revenue, and items credited to revenue are transferred to credit of purchase account. The absence of title to shares valued at £2,000 in the Snaefell Mountain Railway is mentioned; outstanding claims hitherto disputed by the company are also referred to, and criticisms are made on the insufficient accounts kept. On the separate undertaking of the Laxey-Ramsey section the outstanding liabilities are placed at £48,000, and the net revenue account shows a loss of £434 in 1898 and £402 in 1899.

MELDRUM BROS. (LTD.)—Subscriptions are being invited for 50,000 5½ per cent. cumulative £1 preference shares.

OSWESTRY ELECTRIC LIGHTING AND POWER CO. (LTD.)—The annual meeting was held recently. The directors' report stated that the gross

Digitized by Google

profit for 1899 amounted to £318. 8s. 2d., which, with £8. 0s. 1d. from 1898, left an available balance of £326. 8s. 3d. Besides providing for depreciation, £60 has been added to reserve, which is being charged with the cost of renewal and extension of battery, and £12. 0s. 4d. has been written off preliminary expenses, leaving a net disposable balance of £254. 7s. 11d. A dividend at the rate of 4 per cent. is recommended, and £20. 9s. 2d. carried forward.

REUTER'S TELEGRAM CO. (LTD.)—The directors' report states that the amount available for distribution for the year ended Dec. 31 last, after payment of current charges, is £8,304. 5s. 3d., including £29. 5s. from last account. An interim dividend of 2½ per cent. was paid in October, and the directors now declare a dividend of 4s. per share (2½ per cent.), making a total distribution, tax free, of 5 per cent. for the year. This will absorb £4,944. 16s. 8d., and after adding £3,000 to reserve the balance (£309. 8s. 7d.) is to be carried forward.

RUSTON, PROCTOR AND CO. (LTD.)—The directors' report for the year to March 31 states that the profit was £48,159. Deducting depreciation of buildings, plant and machinery, &c. (£9,254), directors' remuneration (£1,200), and debenture interest (£10,469), there remains (including £1,479 brought forward) £28,615, and the directors propose a dividend of 14s. per share (7 per cent. for year) £17,500 ; to equalisation of dividends account, £10,000, carried forward £1,115. The directors consider that, in view of the development of the company's business the capital should be increased to £360,000 by the creation of 10,000 additional shares of £10 each.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee has appointed the 30th inst. a special settling day in the further issue of £150,000 5 per cent. perpetual debenture stock of the *British Electric Traction Co. (Ltd.)*, and has ordered the same, together with the further issue of 3,000 £10 fully-paid shares (Nos. 12,001 to 15,000) of the *Blackpool and Fleetwood Tramroad Co.* to be quoted in the official list. Application has also been made to the committee to appoint a special settling day in, and to grant a quotation to the provisional certificate for £100,000 5 per cent. second debenture stock of the *Edison and Swan United Electric Light Co. (Ltd.)*.

THAMES IRONWORKS, SHIPBUILDING AND ENGINEERING CO. (LTD.)—During the week this company made an issue of 100,000 "B" 6 per cent. cumulative preference shares.

WESTERN TELEGRAPH CO.—An interim dividend of 3s. per share (at the rate of 6 per cent. per annum), free of tax, for the quarter ended March 31 has been declared payable June 22. The transfer books will be closed from June 15 to June 21 inclusive.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LTD.)—At a meeting on Monday the resolutions passed at the meeting on April 11 (reported in our issue of April 13) were confirmed.

NOTES.

WE give in another column some account of the lectures and debates on submarine telegraphic communication which have taken place during the past week at the Society of Arts and the Royal United Service Institution. It has always been a favourite method with advocates of reductions in the charges for cable telegrams—as, for instance, Mr. HENNIKER HEATON and Sir EDWARD SASSOON—to add together the internal land tariffs of the different States which would be transited by a land-line message to any given point, and then to base on this total a claim that the rates for submarine transmission are too high. To say nothing of the innocence of the assumption that foreign countries will accept for international communication their internal rates, which frequently involve a loss, a little more knowledge of the subject would show that the great advantages to this country of the submarine cable connections cannot be maintained without pecuniary loss at rates approximating at all to those of land-lines, even when these lines are highly remunerative.

FIRST of all, on a moderate calculation, a land-line system abroad, with one wire, costs only one-fourth or one-fifth as much as a submarine cable of the same length. Then, the maintenance of the former costs much less than the sea route, which requires expensive cable-ships stationed at various points. Again, when duplication of existing cables is necessary, the new section, with constantly rising prices for material, costs more than the original; whereas an additional wire on a land-line would only involve about one-twentieth the cost of the additional under-sea connection. Further, cables are subject electrically to what is known as "retardation"; aerial wires are not, and can therefore be worked at ten times the speed. In the case of long land lines it may be pointed out that, though they are interrupted for shorter periods as a rule than submarine routes, yet short interruptions are very much more frequent, and certainty of communication is one of the elements vital to the growth of telegraphic traffic to its full capacity. It is curious to note that some of those who have urged the great importance of cable routes being "all-British" should have advocated the use of long land lines, which would pass almost entirely through foreign territories.

IN the issue of the *Financial News* for May 18 is a description of the Riecker electrolytic process for extraction of gold from sulphide ores. According to the writer the process consists in agitating the ore in a finely divided state with a solvent containing sodium chloride and potassium cyanide, and at the same time passing a current of electricity through the mass of ore and water by means of iron anodes, and amalgamated copper cathodes over which mercury is kept in constant flow. The coarser particles of pure gold are said to be directly amalgamated, while the finer particles and the chemically combined gold are dissolved by the cyanide, and then electro-chemically deposited upon the cathodes by means of the current passing through the cell. The gold amalgam obtained upon the cathode plates is stated to be exceedingly dense, and able to resist the attrition to which the agitation of a large body of ore suspended in water subjects it. The cost of treatment amounts to 6s. 8d. per ton, and the process is about to receive trial upon an extended scale at the South Kalgurli Mine in Western Australia.

THERE have been so many similar processes for extracting gold invented, tried, and never more heard of, that we wait for further information concerning the trials of the Riecker process at Kalgurli before pronouncing any decision upon it. That some of the gold can be extracted from ores by such a method is well known—that practically all the gold can be extracted at a cost which will compete with the methods now in use, remains to be proved. In view of the closing paragraph of the article in the *Financial News*, which conveys a gentle hint that the shares of the company owning the Riecker patents may prove a splendid speculative investment, we should like to state that there have been several patents for processes

Digitized by Google

practically identical with the "Riecker" process granted in past years, and that if the latter process is as successful as its inventors and owners expect, the question of patent validity and priority is certain to arise. For the guidance of those interested in the subject we may name the processes of Edwards (1894), of Danckwardt (1894), and of Hannay (1890), as processes which make use of agitators, crushed ore, amalgamated cathodes, and an electrolyte of potassium cyanide, while the Peletan-Clerici process described by Major-Gen. WEBBER before the Institution of Electrical Engineers in January, 1898, is another process of a similar kind.
